While engaged in studying experimentally the connections of the cells of Clarke's column with the ascending tracts of the spinal cord in the monkey, I was surprised to find that after hemisection in the lower dorsal region the sensory disturbances produced in no way corresponded with those already obtained by eminent observers.

I was therefore led to continue my experiments, and, by the kind permission of Prof. Schäfer, I carried them out in the Physiological Laboratory of University College. My thanks are also due to him for much valuable advice and assistance.

The subject is one of great importance from a scientific, as well as from a clinical, point of view. Some years ago, a case occurred in my practice which tended to shake my faith in the absolute truth of the doctrine of complete and immediate decus-

Digitized by Google

sation of sensory impulses in the spinal cord, as taught by Brown-Séquard.

The experiments which I have performed exhibit the following principal points of interest:—

(1) Return of associated movements after complete destruction of the crossed pyramidal tract below the lesion.

(2) That all sensory impulses do not decussate in the cord—in fact, they appear to show that certain sensory impulses, *e.g.* touch, the muscular sense, and localization in space, pass chiefly up the same side, painful impressions up both sides. A peculiar condition known as "allochiria" occurs after hemisection.

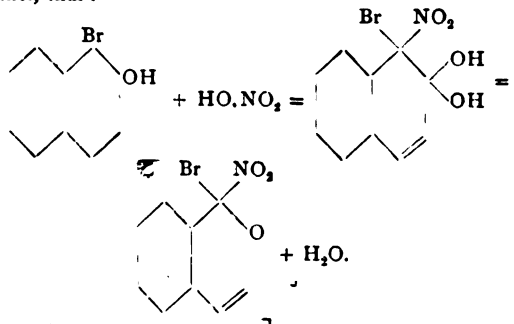
(3) The vaso-motor disturbances are *on the same side as the lesion*, and consist of vaso-dilation, swelling of the foot, and redness with rise of temperature of the skin of the foot (as compared with the opposite side), and fall of temperature in the popliteal space on the side of the lesion, due, no doubt, to paralysis of the muscles.

(4) The degenerations above and below the lesion are limited to the same side when the injury is perfectly unilateral. There are certain facts connected with the degenerations which serve to show the origin and course of certain long and short tract fibres.

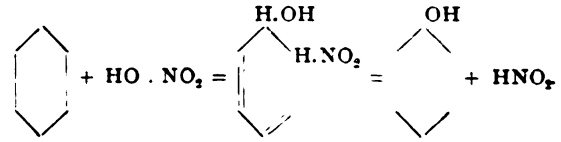
(5) Stimulation of the cortex cerebri on both sides some weeks or months after the hemisection had been performed gave, as a rule, *results* which showed that the block in the spinal cord produced by the hemisection still existed, although there had been a very complete return of associated movements.

(6) In one case ablation of the leg area on the same side as the lesion in the spinal cord was performed many months afterwards.

Chemical Society, May 21.—Prof. A. Crum Brown, F.R.S., President, in the chair.—The following papers were read:—Bromo-derivatives of betanaphthol, by H. E. Armstrong and E. C. Rossiter. The authors have completed the study of the compounds formed on brominating betanaphthol, to which they have referred in two previous notices (Chem. Soc. Proceedings, 1889, p. 71; 1890, p. 32). In the present paper they give directions for preparing tri- and tetra-bromobetanaphthol, and summarize the properties of the bromobetanapthols. The entire product of the action of bromine in excess on betanaphthol, has been carefully examined without any substance having been discovered which affords 1 : 2 : 3-bromophthalic acid on oxidation; the discrepancy between the authors' observations and the earlier experiments of Smith and Meldola, therefore, yet remains to be discovered.—The action of nitric acid on naphthol derivatives as indicative of the manner in which nitration is effected in the case of benzenoid compounds generally: the formation of nitro-keto-compounds, by H. E. Armstrong and E. C. Rossiter. The chloro- and bromo-derivatives of betanaphthol when warmed with nitric acid are converted into derivatives of betanaphthoquinone; but the formation of these compounds is preceded by that of an unstable intermediate compound. These intermediate compounds, when carefully heated, are converted into derivatives of betanaphthaquinone. Thus, when nitric acid is added to dibromobetanaphthol, suspended in acetic acid, a clear solution is obtained which, after a short time, deposits a crystalline substance; if quickly evaporated by filtration, this product is almost colourless, but it decomposes when kept, becoming yellow. This compound, when treated with alkali, yields bromonitronaphthol. Bromobetanaphthol, in like manner, yields α_1-nitrobetanaphthol, and the tri- and tetra-bromo-derivatives yield di- and tri-bromonitrobetanaphthol. The authors are of opinion that the intermediate compounds in question are nitro-bromo-keto-derivatives, and that their formation affords evidence that the elements of nitric acid first become added to the bromonaphthol, thus:—



The theory that the formation of such addition-compounds precedes that of nitro-compounds generally, appears to afford a satisfactory explanation of a number of well-known facts which hitherto have remained unexplained. The non-production of nitro-compounds from paraffins and their derivatives appears as the natural consequence of the inability of paraffins to form addition-compounds. The theory affords a simple explanation of the formation of nitro-derivatives of *phenols* on nitrating hydrocarbons, for if the addition-compound lose $H.NO_2$ instead of H.OH a phenol would result, thus—



An agent which would tend to withdraw water from the addition-compound would increase the production of nitro-compound and diminish that of phenol; and it is known that when a mixture of nitric and sulphuric acids is used, there is less of the phenol derivative produced than when nitric acid alone is employed. A compound like the addition-compound of benzene, represented above, would obviously be unstable, and prone to undergo oxidation; hence the explanation of the large amount of nitrous fume produced on nitrating benzene. The non-production of resinous matters when sulpho-acids are treated with nitric acid to form the corresponding nitro-compound by displacement of the SO_3H group by NO_2 is also elucidated by the authors' theory; the addition-compound formed in such a case would very readily break up into sulphuric acid and the nitro-derivative.—A new method of preparing nitro-derivatives, and the use of nitrogen dioxide as a nitrating agent, by H. E. Armstrong and E. C. Rossiter. The authors find that the unstable compounds formed by the addition of the elements of nitric acid to the bromo-derivatives of betanaphthol yield nitro-derivatives of the naphthol on treatment with alkali, a bromine atom becoming displaced by NO_2. On treating the addition-compound with sulphurous acid, a practically theoretical yield of the nitronaphthol is obtained; this method appears to be of general application. The authors have been naturally led to study the action of nitrogen-dioxide, NO_2, on unsaturated compounds of various kinds, in the hope of obtaining addition-compounds which by loss of HNO_2 would pass over into nitro-derivatives of the substances treated. They find that such addition-compounds are obtained, and on treatment with alkali and reducing-agents yield nitro-compounds. Thus betanaphthol yields 75 per cent. of its weight of nitro-betanaphthol; alphanaphthol behaves similarly. Phenol yields ortho- and para-nitrophenol. The authors propose to study the action of nitric acid and nitrogen dioxide on unsaturated compounds generally from the point of view indicated in this and the previous note.—Nitrification, by R. Warington. The first section of the paper describes early experiments, showing the existence of an agent producing only nitrites, and the means of separating it from soil. Successive cultivation in ammoniacal solutions made permanently alkaline with disodium carbonate was found to be a certain method of obtaining a purely nitrous agent. Pasture soil yielded the nitrous agent more readily than arable soil. The nitrous organism was isolated by the dilution method. Cultivations were made in an ammonium chloride solution with calcium carbonate. The nitrous organism oxidizes ammonia to nitrous acid, and has no effect on nitrites. It produces nitrous acid in solutions of asparagine, milk, urine, and urea. Grown in broth containing calcium nitrate, it does not reduce the nitrate to nitrite. It requires no organic matter for its nutrition, and is apparently capable of assimilating carbon from acid carbonates. The presence of either calcium or sodium acid carbonate distinctly favours nitrification; neutral sodium carbonate greatly hinders nitrification. The nitrous organism occurs as nearly circular corpuscles, which stain deeply. It also occurs as oval cocci, the ends occasionally more or less truncated. The remainder of the paper deals with the nitric organism. The results show that the nitric organism develops freely in inorganic solutions containing potassium nitrite, phosphates, &c., especially if supercarbonates are present. Monosodium carbonate, 1–4 grams per litre, exerted a very favourable influence; 6 grams per litre, a retarding influence. Disodium carbonate greatly hinders the action. The nitric organism produces neither nitrites nor nitrates in ammoniacal solution. In the absence of

Digitized by Google

ammonia, it energetically converts nitrites into nitrates; the presence of ammonia is apparently a great hindrance to its action. An attempt to isolate the organism failed. The nitrification performed by soil thus appears to be the work of two organisms, one of which oxidizes ammonia to nitrite, while the other oxidizes nitrite to nitrate.

Geological Society, June 10.—Sir Archibald Geikie, F.R.S., President, in the chair.—Before the commencement of the general business, Prof. Blake rose on behalf of those present at the meeting to congratulate the President on the honour that it had pleased Her Majesty to confer upon him. No one who knew him could fail to appreciate how thoroughly it was deserved; and the Geological Society would doubtless feel also the honour conferred on their science in the person of their President and the head of the Geological Survey of the United Kingdom.—The following communications were read:—Note on some recent excavations in the Wellington College district, by the Rev. A. Irving.—Notes on some post-Tertiary marine deposits on the south coast of England, by Mr. Alfred Bell. Communicated by Mr. R. Etheridge, F.R.S. The author's object in this paper is to trace the successive stages in the development of the present coast of the north side of the English Channel, and to ascertain the sources of the diversified faunas. The first traces of marine action on the south coast in post-Tertiary times, are found on the foreshore in Bracklesham Bay. The author's reading of the section is somewhat different from that of the late Mr. Godwin-Austen; and he divides the marine series into (1) an estuarine clay with Mollusca common to estuarine flats; (2) a compact hard mud; and (3) a bed of fine sandy silt with many organisms. These beds indicate a change from estuarine to deep-water conditions. A full list of the Selsey fossils is given, including, amongst other animals, upwards of 200 Mollusca. Of 35 species of Mollusca not now living in Britain, the majority exist in Lusitanian, Mediterranean, or African waters; furthermore, nearly 45 per cent. of the Mollusca are common to the older Crags of the eastern counties. The author considers the fauna of the Portland Bill shell-beds to indicate the further opening of the Channel subsequent to the formation of the Severn Straits, and believes that this fauna represents the deposits wanting between the Selsey mud-deposits and the erratic blocks which, according to him, overlie the mud; these Portland shells indicate an intermediate temperature, "rather southern than northern," according to Dr. Gwyn Jeffreys. In conclusion, details concerning still newer beds are given, and lists of fossils found therein; and the author observes that there is no evidence to show when the English Channel finally opened up, beyond the suggestion of Mr. Godwin-Austen that, if the Sangatte beds and the Coombe Rock are of the same period, it must have taken place after their formation. After the reading of this paper some remarks were made by Mr. Etheridge, Mr. C. Reid, Prof. Hull, and the author.

Mathematical Society, June 11.—Prof. Greenhill, F.R.S., President, in the chair.—The following communications were made:—Systems of spherical harmonics, by E. W. Hobson.—On the motion of a liquid ellipsoid under its own attraction, by Dr. M. J. M. Hill.—On certain properties of symmetric, skew-symmetric, and orthogonal matrices, by Dr. H. Taber.—An application of the method of images to the conduction of heat, by G. H. Bryan.—A property of the circum-circle, by R. Tucker.

CAMBRIDGE.

Philosophical Society, June 1.—Prof. G. H. Darwin, President, in the chair.—The following communications were made:—On the part of the parallactic series of inequalities in the moon's motion which is a function of the ratio of the mean motions of the sun and moon, by Mr. Ernest W. Brown.—On Pascal's hexagram, by Mr. H. W. Richmond. The author applies Cremona's method of deriving the hexagram by projection of the lines on a nodal cubic surface from the node. By use of a new form of the equation to this surface the equations of the lines are obtained in a perfectly symmetrical form, and their properties thence developed.—A linkage for describing lemniscates and other inverses of conic sections, by Mr. R. S. Cole.—Some experiments on liquid electrodes in vacuum tubes, by Mr. C. Chree. This paper describes some experiments undertaken at the suggestion of Prof. J. J. Thomson on the electric discharge through vacuum tubes in which one or both of the electrodes were liquid surfaces. The liquids employed were mercury and sulphuric acid. The electrodes when solid were of platinum or aluminium. Observations were taken of the differences presented by the discharge when the substance of an electrode was altered. The experiments were mostly at low gaseous pressures, and included observations on the character of the phosphorescence then accompanying the discharge.—On gold-tin alloys, by Mr. A. P. Laurie.—Note on a problem in the linear conduction of heat, by Mr. G. H. Bryan.

EDINBURGH.

Royal Society, June 1.—Prof. Chrystal, Vice-President, in the chair.—Prof. Tait communicated a paper, by Prof. Piazzi Smyth, on two series of enlarged photographs, one in the visible, the other in the invisible, of the violet of the solar spectrum. The paper was accompanied by the photographs. The observations include part of the spectrum as previously observed by Mr. Smyth in the summer of 1884, and extend to an extreme distance in the invisible violet. The previous observations were included in sixty plates; in the present series, twelve more plates are added in the violet region, and two independent photographs of each part have been taken. The photographs agree with those of Prof. Rowland in indicating that the Fraunhofer line, "little *d*," is either entirely absent now from the solar spectrum, or has become very unimportant.—Mr. R. Kidston read a paper on the fossil plants of the Kilmarnock, Galston, and Kilwinning coal-field in Ayrshire. All the species which are described in the paper belong, with one exception, to the Lower Coal-measures.—Prof. Tait communicated the second and third parts of a paper, by Prof. C. G. Knott, on some relations between magnetism and twist in iron, nickel, and cobalt. Part II. contains a continuation of former experiments on the twists produced in the magnetic metals when they are under the combined influence of circular and longitudinal magnetizations. A rectangular rod of cobalt twists, like nickel, left-handedly, when a current is passed along it in the direction of magnetization. Iron twists right-handedly, unless strong fields are employed. There is no reversal of the twist in nickel when strong fields are used, but a maximum can be reached. The magnitude of the twist which is produced by a reversal of one force depends upon which force is reversed. In general, reversal of the longitudinal field produces the greater effect; but iron and nickel, in low fields, twist most when the current is reversed. Hysteresis is very evident in all the phenomena. Evidence is given in this part in confirmation of the truth of an expression, which was given in Part I., for the twist in terms of the elongations in a thin-walled tube of given radius. Part III. contains a discussion of the magnetic consequences of twisting a magnetized wire—more especially a circularly-magnetized wire. The peculiar manner in which the magnetic change sometimes lags behind the stress, sometimes shoots ahead of it, is fully investigated. This effect is found to depend upon the strength of the current, on the amount of the twist, and on the amount of vibration to which the wire is subjected. The longitudinal polarity which is acquired when a wire carrying a current is twisted appears to be high in comparison with the intensity induced at the circumference of the wire. This seems to indicate the existence of molecular groupings which alter their configuration when subjected to change of stress or of magnetic force. The effects which are observed when an apparently demagnetized wire is subjected to twist suggest that a magnetized wire may in certain circumstances consist of alternate layers of opposite polarities. Any stress which acts differently on these layers will produce powerful magnetic effects. From his own experiments and those of other observers, Dr. Knott concludes that the first effect of a shearing stress on the molecular groupings is not only to increase the average intensity in the direction of the magnetizing force, but also to bring into prominence a relatively high intensity in directions at right angles to it.—Dr. Buchan communicated a paper by Mr. R. T. Omond, Superintendent of the Ben Nevis Observatory, and by Mr. A. Rankin, assistant observer, on the winds of Ben Nevis. The exact determination of northerly winds is not very easy, owing to the shape of the hill. The cliff, 2000 feet in height, which forms the northern face, breaks these winds up, and makes them squally and uncertain. Some may be entered on the record as north when they should really have been entered as north-east or north-west. Southern winds are on the whole slightly more frequent than northerly winds are. At sea-level the most frequent wind is west; and south-west, west, and north-west include nearly half of the total observations—more than half if calms are excluded. These low-level winds are in exact accord-

Digitized by Google

ance with the distribution of barometric pressure over the British Isles according to the Buys Ballot's law, which asserts that the winds blow counter-clockwise round areas of low pressure, such an area lying to the north of the British Isles. But the Ben Nevis winds do not fit in with such a distribution of pressure at all, which indicates that isobars drawn at the level of Ben Nevis (4400 feet) have directions differing entirely from the directions of sea-level isobars. In other words, the distribution of average barometric pressure which extends over the North Atlantic and North-western Europe, and dominates the surface wind over that area, does not in this country extend to a vertical height of one mile. Precautions were taken to make certain that this difference was not due to a difference between the methods of observation at Ben Nevis and at low-level stations. If a cyclonic storm of small area is lying to the north-eastward, the sea-level winds are west or north-west; but the Ben Nevis winds may be north-east, blowing straight out from the centre of the area of low pressure. In larger storms the Ben Nevis winds are practically identical with the sea-level winds, which indicates that a storm has a vertical extent proportionate in some way to the horizontal area which it covers. The outflowing wind seldom or never occurs when the centre is to the south or west, but only when it is to the north or east; and it is most strongly marked when an anticyclone lies on the other side. The outflowing current seems to carry the ascending air of the cyclone to the descending anticyclonic regions. The non-observation of the outward current when the centre of the cyclone lies on the south or west may be due to the fact that it passes at a higher level than the top of the mountain, for it then consists of air passing from hotter to colder regions, which will presumably rise to a higher level. The veering of the wind at great heights, which should occur according to the usual theory of cyclones, is very rarely observed.—Dr. Crum Brown read a paper, by Dr. A. B. Griffiths, on the blood of the Invertebrata.

PARIS.

Academy of Sciences, June 15.—M. Duchartre in the chair.—On the deformation and extinction of isolated or periodic aërial waves propagated in the interior of delivery tubes without water and of indefinite length, by M. J. Boussinesq.—On a volatile compound of iron and carbonic oxide-iron-carbonyl, and on nickel-carbonyl, by M. M. Berthelot. The author finds that iron, taken in a particular state, combines directly with carbonic oxide at ordinary temperatures (about 45° C. gives the best results) to form a very volatile compound. The required state is attained by reducing precipitated iron peroxide by hydrogen, or by decomposing ferrous oxalate by heat, and completing the reduction with hydrogen. Iron-carbonyl is analogous to nickel-carbonyl, discovered by Mond, Lang, and Quincke (Journ. Chem. Soc., vol. lvii. p. 749, 1890). M. Berthelot has investigated the stability of the latter compound and its reactions with oxygen, sulphuric acid, ammonia, and nitrogen dioxide.—*Résumé* of meteorological observations made at Ecorchebœuf, near Dieppe, from 1873 to 1882 by M. J. Reiset.—Observations of Wolf's periodic comet, made at Paris Observatory (West Tower equatorial), by M. G. Bigourdan. Two observations for position were made on June 12. It is remarked that the comet is a round nebulosity about 20′ in diameter, and having a magnitude 13·3.—Observations of the new asteroid (310) made at Paris Observatory with the East Tower equatorial, by Mdlle. D. Klumpke. An observation for position was made on June 12.—Eclipse of the sun of June 6; observations made at Lyons Observatory, by MM. Gonnessiat and Le Cadet. Measures were made of times of contact.—Observations of Wolf's periodic comet (1884, III.), made at Algiers Observatory with the Foucault telescope of 0·50 metres aperture, by MM. Rambaud and Sy. Eight observations for position were made between May 15 and June 8.—Eclipse of the sun of June 6, observed at the Observatory of the Flammarion Scientific Society at Marseilles, by M. Jacques Léotard.—On the two forms in which the co-ordinates of the surface of the fourth degree, described by the summits of cones of the second order which pass through six given points, are expressed by means of θ functions of two arguments, by M. F. Caspary.—On an electric indicator for the detection of small variations of pressure in currents of gas, by MM. G. and L. Richard.—Researches on the application of the measure of rotatory power to the determination of compounds formed by aqueous solutions of mannite, with acid molybdates of soda and ammonium, by M. D. Gernez. By measuring the proportions of salts in solution which give the maximum rotatory effect on polarized light, the author arrives at the molecular formula of the compounds formed.—On quinethyline, a homologous base of quinine, by MM. E. Grimaux and A. Arnaud.—On ureides derived from normal acids, by M. C. Matignon.—Mode of formation of methyl-campho-carbonates of methyl and ethyl, by M. J. Minguin.—On nitro-cyanacetic ethers, by M. P. Th. Muller.—Bleaching of cotton by oxygenated water, by M. Prud'homme. The addition of calcined magnesia to oxygenated water improves the bleaching properties of the latter. According to the author, the superiority of the results obtained is due to the formation of a peroxide of magnesium.—*Rôle* of the nucleus in the formation of the fundamental muscular reticulum of the larva of Phrygane, by M. G. Bataillon.—On a special disposition of the eyes in *Pulmonara basommatophoræ*, M. Victor Willem.—Experimental contribution to the study of growth, by M. Henry de Varigny.—On a cryptogamic disease of the *Acridium peregrinum*, by M. L. Trabut.—On the existence of a little Miocene vertebrate fauna in the rocks of the Saône valley at Gray, and at Mont d'Or Lyonnais, by M. MESSRS. MACMILLAN & CO.'S NEW BOOKS.

SECOND EDITION OF MARSHALL'S PRINCIPLES OF ECONOMICS.
Just Ready, Vol. I., 8vo, 12*s.* 6*d.* net.

PRINCIPLES OF ECONOMICS.

By ALFRED MARSHALL, M.A., Professor of Political Economy in the University of Cambridge, Fellow of St. John's College, Cambridge, sometime Fellow of Balliol College, Oxford. 2 Vols.

Some Press Notices of the First Edition.

TIMES:—"This great treatise on economic science bids fair to take for the present generation the place which Mill's work took for the generation of forty years ago. It is a contribution of capital importance to the higher literature of economic science. . . . What is still more characteristic of the work is its wide command and felicitous application of 'curious facts,' its searching analysis of the mechanisms of business of all kinds, and its masterly treatment of human action and motive in their bearing on economical problems."

OBSERVER:—"In a sense, Prof. Marshall's work is the most striking book of the season."

NATURE:—"The uniformities of action resulting from such measurable motives may be regarded as the laws of motion in what Jevons called the *mechanics of industry*—a science which Prof. Marshall has cultivated with more success than any of his predecessors, owing to an unexampled combination of antithetical powers, the comprehensive grasp of mathematical reasoning, and the careful handling in detail of the observed facts. . . . We should like to dwell upon the practical importance of these conceptions. But it is impossible here to analyze a work almost every page of which presents a new idea."

GLASGOW HERALD:—"It is serious and thorough in the last degree; there is not a vestige of slipshod reasoning in it, yet it is extremely readable, and the hardest-headed business man might find its suggestions of practical value."

MANCHESTER GUARDIAN:—"The author has contrived, with a success which has not been approached since the appearance of Mill's great work, to combine the accurate complexity of a technical treatise with the suggestive interest of a practical contribution to social science."

SCOTSMAN:—"There can be no question that it is the most important and valuable contribution to the general theory of political economy, whether in this country or abroad, since the publication of J. S. Mill's 'Principles.' But although the book is in many respects profoundly original, there is no affected straining after originality, or irritating and complacent exposure of the errors and defects of others."

ACADEMY:—"Advances the position of the science as it were by leaps and bounds."

POLITICAL SCIENCE QUARTERLY (Prof. J. P. CLARK):—"Adding its own special contribution to the general result of past and present thinking, it presents the science of economics as it stands to-day in a nearer approach to unity than has seemed to be possible."

ANNALS OF THE AMERICAN ACADEMY (Prof. J. H. GIDDINGS):—"It does for political economy in the last decade of the nineteenth century what Smith did in the last quarter of the eighteenth, and what Mill did after the discussion of two generations had apparently fixed the fundamental lines. It gathers and sifts the store of economic knowledge. It reconstructs the whole body of doctrine on broader grounds, and in that new spirit at once more liberal and more severely scientific, that has characterized every department of thought in these later years."

SATURDAY REVIEW:—"This book is, without doubt, among the most important contributions to political science made by English authors within recent times. . . . Mr. Marshall exhibits it as a true and living branch of politics, as the study not merely of the logical consequences of competition between wealth-seeking individuals, but of the wealth of nations in the fullest sense. . . . The result is that his book, without any sacrifice of scientific exactness, has a literary merit and a human interest which are exceedingly rare in works on the subject, and that the dangers of misapprehension and perversion are reduced to the lowest possible degree."

THE FIRST VOLUME OF A NEW SERIES OF ELEMENTARY COMMERCIAL CLASS-BOOKS.
Globe 8vo, 3*s.* 6*d.*

THE HISTORY OF COMMERCE IN EUROPE. By H. DE B. GIBBINS, M.A.,

Assistant Master at the High School, Nottingham. With Maps.

*** This little work is an instalment of a series of books on Commercial Education which have been designed to meet the growing demands for Commercial Education in our Higher Schools. Among the subjects included will be Commercial Law, Commercial Arithmetic, Commercial Geography, etc. Care will be taken to make the series as thoroughly comprehensive and useful as possible. The present volume is the only history of European commerce that exhibits the growth and development of trade from the earliest times to the present day in a concise and complete form. The author has aimed at connecting the history of commerce with the growth of each nation in political power.*

NEW VOLUMES OF MACMILLAN'S MANUALS FOR STUDENTS.

A NEW TEXT-BOOK OF CRYSTALLOGRAPHY.
Crown 8vo, Cloth, 6*s.*

ELEMENTS OF CRYSTALLOGRAPHY FOR STUDENTS OF CHEMISTRY, PHYSICS, AND MINERALOGY. By GEORGE HUNTINGDON WILLIAMS, Ph.D., Assistant Professor in the Johns Hopkins University. Crown 8vo.

*** A concise and elementary statement of the general principles of Crystallography, not intended as a complete treatise, but to furnish so much information on the subject as may be of service to students of other but allied branches.*

Crown 8vo, Cloth, 10*s.* 6*d.*

LESSONS IN ELEMENTARY BIOLOGY. By T. JEFFREY PARKER, B.Sc., F.R.S., Professor of Biology in the University of Otago, Dunedin, New Zealand. Illustrated.

NEW EDITION, REVISED.
Crown 8vo, Cloth, 10*s.* 6*d.*

A COURSE OF PRACTICAL INSTRUCTION IN BOTANY. By F. O. BOWER, D.Sc., F.R.S., Regius Professor of Botany, Glasgow.

NATURE:—"Everyone perusing the volume must be impressed with the high standard of its educational value. Teacher and student in this country are alike to be congratulated upon its publication. We envy a student commencing to work with such a guide, and we are greatly mistaken if its effect is not very rapidly felt in the botanical teaching of the country."

ACADEMY:—"The work is one which should be in the hands of every practical botanist."

MACMILLAN AND CO., LONDON.

MUSEUMS' ASSOCIATION.

The ANNUAL MEETING of this ASSOCIATION will be held in CAMBRIDGE on JULY 7, 8, and 9.

PRESIDENT:
J. WILLIS CLARK, M.A. (Superintendent of the University Museum of Zoology and Comparative Anatomy, Cambridge, and Registrary of the University).

HON. TREASURER:
Alderman W. H. BRITTAIN (Sheffield).

GENERAL SECRETARIES:
H. M. PLATNAUER, B.Sc. (York).
T. J. MOORE, Cor.M.Z.S. (Liverpool).

LOCAL SECRETARY AND TREASURER:
S. F. HARMER, M.A. (Fellow of King's College).

For Particulars apply to H. M. PLATNAUER, The Museum, York.

BALLIOL COLLEGE, CHRIST CHURCH, AND TRINITY COLLEGE, OXFORD.

NATURAL SCIENCE SCHOLARSHIPS AND EXHIBITIONS.

A combined Examination for Natural Science Scholarships and Exhibitions will be held by the above Colleges, beginning on TUESDAY, DECEMBER 1, 1891.

Three Scholarships and Two Exhibitions will be offered, the Scholarships being worth £80 a year.

The subjects for examination will be Physics, Chemistry, and Biology, but Candidates will not be expected to offer themselves in more than two of these.

Particulars may be obtained by application to A. VERNON HARCOURT, Christ Church, Oxford.

UNIVERSITY OF GLASGOW.

THE JOHN ELDER CHAIR OF NAVAL ARCHITECTURE (INCLUDING MARINE ENGINEERING).

Owing to the death of the late Occupant, the Chair is now Vacant. Candidates intending to apply for the Vacancy are invited to lodge with the Secretary of the University Court, Mr. ALAN E. CLAPPERTON, 91 West Regent Street, Glasgow, 20 Printed Copies of their Applications and any Relative Testimonials, on or before JULY 31 Next.

THE AGRICULTURAL COLLEGE, ASPATRIA.

PRINCIPAL—DR. H. J. WEBB, B.Sc.

Thorough practical and scientific Training in Agriculture. Preparation for the Colleges. Students gained the First, Third, and Fourth Scholarships of the Royal Agricultural Society, 1888; First in Agriculture Junior Scholarships, 1889; First in Agriculture Senior Scholarships, 1890.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.

The post of DEMONSTRATOR of PHYSIOLOGY is now Vacant. Salary £100.

Applications, with Testimonials, to be sent to the DEAN not later than JULY 15.

E. NETTLESHIP, Dean.

UNIVERSITY COLLEGE OF WALES, ABERYSTWYTH.

An ASSISTANT LECTURER and DEMONSTRATOR in BIOLOGY will be required next Session. Duties mainly Botanical.

Particulars can be obtained from Prof. AINSWORTH DAVIS, to whom applications should be sent on or before JULY 18.

TWO ENTRANCE SCHOLARSHIPS in NATURAL SCIENCE, of the value of 125 Guineas (*i.e.* a Free Admission) and £80, are awarded annually in OCTOBER at ST. THOMAS'S HOSPITAL MEDICAL SCHOOL, London, S.E.

For Particulars, apply to Mr. G. REDDLE, Medical Secretary.

E. NETTLESHIP, Dean.
G. H. MAKINS, Vice-Dean.

A GRADUATE (B.A., B.Sc., Hons., Lond.)

of four and a half years' Teaching Experience, requires a Mastership in Natural Science. Address, "F." News's Library, Blackheath S.E.

Sale by Auction.

THE CELEBRATED, EXTENSIVE, CHOICE, AND VALUABLE COLLECTION OF SHELLS FORMED BY THE LATE SIR DAVID W. BARCLAY, BART.

MR. J. C. STEVENS has been favoured with instructions to Sell by Auction, at his Great Rooms, 38 King Street, Covent Garden, on MONDAY, JULY 6, and three following days, at half-past 12 precisely each day, the *entire* celebrated, extensive and valuable Collection of Shells formed by the late Sir DAVID W. BARCLAY, Bart., together with the Cabinets and Conchological Library, *without the least Reserve*. The Collection contains nearly all the rarities, and is especially rich in *Conus*, *Cypræa*, *Oliva*, *Mitra*, *Voluta*, *Fasciolaria*, *Helix*, and *Cyclostoma*, &c., and includes many *types* of species, *some of which are unique*. The late owner was for upwards of a century forming the above, during which period he was constantly acquiring the best specimens obtainable, and his undoubted great wealth enabled him to form the grand Collection (30,000 fine specimens) now offered for public competition.

On view the Saturday prior, 10 till 4, and Mornings of Sale, and Catalogues had.

N.B.—The entire Collection will be offered at this Sale, no portion having been disposed of privately.

MINERALOGY.

SAMUEL HENSON,

97 REGENT STREET, LONDON, W.

ESTABLISHED 1840. *Late 277 STRAND.*

MESSRS. MACMILLAN & CO.'S NEW BOOKS.

SECOND EDITION, THOROUGHLY REVISED, OF MARSHALL'S PRINCIPLES OF ECONOMICS.

Just Ready, Vol. I., 8vo, 12s. 6d. net.

PRINCIPLES OF ECONOMICS.

By ALFRED MARSHALL, M.A., Professor of Political Economy in the University of Cambridge, Fellow of St. John's College, Cambridge, sometime Fellow of Balliol College, Oxford. 2 Vols.

*** A copy of the Second Edition will be supplied to any purchaser of the First Edition who forwards his copy of the first edition together with a remittance for 7s. to Macmillan and Co. before September 30, after which date this offer will be withdrawn.*

Some Press Notices of the First Edition.

TIMES:—"This great treatise on economic science bids fair to take for the present generation the place which Mill's work took for the generation of forty years ago. It is a contribution of capital importance to the higher literature of economic science. . . . What is still more characteristic of the work is its wide command and felicitous application of 'curious facts,' its searching analysis of the mechanisms of business of all kinds, and its masterly treatment of human action and motive in their bearing on economical problems."

OBSERVER:—"In a sense, Prof. Marshall's work is the most striking book of the season."

NATURE:—"The uniformities of action resulting from such measurable motives may be regarded as the laws of motion in what Jevons called the *mechanics of industry*—a science which Prof. Marshall has cultivated with more success than any of his predecessors, owing to an unexampled combination of antithetical powers, the comprehensive grasp of mathematical reasoning, and the careful handling in detail of the observed facts. . . . We should like to dwell upon the practical importance of these conceptions. But it is impossible here to analyze a work almost every page of which presents a new idea."

GLASGOW HERALD:—"It is serious and thorough in the last degree; there is not a vestige of slipshod reasoning in it, yet it is extremely readable, and the hardest-headed business man might find its suggestions of practical value."

MANCHESTER GUARDIAN:—"The author has contrived, with a success which has not been approached since the appearance of Mill's great work, to combine the accurate complexity of a technical treatise with the suggestive interest of a practical contribution to social science."

SCOTSMAN:—"There can be no question that it is the most important and valuable contribution to the general theory of political economy, whether in this country or abroad, since the publication of J. S. Mill's 'Principles.' But although the book is in many respects profoundly original, there is no affected straining after originality, or irritating and complacent exposure of the errors and defects of others."

ACADEMY:—"Advances the position of the science as it were by leaps and bounds."

POLITICAL SCIENCE QUARTERLY (Prof. J. P. CLARK):—"Adding its own special contribution to the general result of past and present thinking, it presents the science of economics as it stands to-day in a nearer approach to unity than has seemed to be possible."

ANNALS OF THE AMERICAN ACADEMY (Prof. J. H. GIDDINGS):—"It does for political economy in the last decade of the nineteenth century what Smith did in the last quarter of the eighteenth, and what Mill did after the discussion of two generations had apparently fixed the fundamental lines. It gathers and sifts the store of economic knowledge. It reconstructs the whole body of doctrine on broader grounds, and in that new spirit, at once more liberal and more severely scientific, that has characterized every department of thought in these later years."

SATURDAY REVIEW:—"This book is, without doubt, among the most important contributions to political science made by English authors within recent times. . . . Mr. Marshall exhibits it as a true and living branch of politics, as the study not merely of the logical consequences of competition between wealth-seeking individuals, but of the wealth of nations in the fullest sense. . . . The result is that his book, without any sacrifice of scientific exactness, has a literary merit and a human interest which are exceedingly rare in works on the subject, and that the dangers of misapprehension and perversion are reduced to the lowest possible degree."

THE FIRST VOLUME OF A NEW SERIES OF ELEMENTARY COMMERCIAL CLASS-BOOKS.

Globe 8vo, 3s. 6d.

THE HISTORY OF COMMERCE IN EUROPE. By H. DE B. GIBBINS, M.A.,

Assistant Master at the High School, Nottingham. With Maps.

*** This little work is an instalment of a series of books on Commercial Education which have been designed to meet the growing demands for Commercial Education in our Higher Schools. Among the subjects included will be Commercial Law, Commercial Arithmetic, Commercial Geography, and care will be taken to make the series as thoroughly comprehensive and useful as possible. The present volume is the only history of European commerce that exhibits the growth and development of trade from the earliest times to the present day in a concise and complete form. The author has aimed at connecting the history of commerce with the growth of each nation in political power.*

WITH PREFACE BY DR. A. R. WALLACE.

8vo, Cloth, 14s. net.

THE HISTORY OF HUMAN MARRIAGE. By EDWARD WESTERMARCK, Ph.D.,

Lecturer on Sociology at the University of Helsingfors.

I have seldom read a more thorough or a more philosophic discussion of some of the most difficult, and at the same time interesting, problems of anthropology. . . . On some points Mr Westermarck has arrived at different and sometimes diametrically opposite conclusions from those of Darwin, Spencer, Morgan, Tylor, Lubbock, and he has done so after a most complete and painstaking investigation of all the available facts.

With such an array of authority on the one side and a hitherto unknown student on the other, it will certainly be thought that all the probabilities are against the latter. Yet I venture to anticipate that the verdict of independent thinkers will, on most of these disputed points, be in favour of the new comer who has so boldly challenged the conclusions of some of our most esteemed writers. Even those whose views are here opposed will, I think, acknowledge that Mr. Westermarck is a careful investigator and an acute reasoner, and that his arguments, as well as his conclusions, are worthy of the most careful consideration.

Every reader of the work will admire its clearness of style and the wonderful command of what is to the author a foreign language.—From Dr. WALLACE's Preface.

NEW PART OF MR. BUCKTON'S MONOGRAPH OF THE CICADÆ.

Now Ready, Part VI., 8vo, Paper Covers, 8s. net.

MONOGRAPH OF THE BRITISH CICADÆ OR TETTIGIDÆ. Illustrated

by more than Four Hundred Coloured Drawings, by GEORGE BOWDLER BUCKTON, F.R.S.

Parts I., II., III., IV., and V. already Published, 8s. net each; or Parts I.–IV. bound in Vol. I., 33s. 6d. net.

R. FRIEDLAENDER UND SOHN,

Berlin, N.W., Carlstrasse 11.

Just Published.

DR. MAX BLANCKENHORN.

GRUNDZÜGE DER GEOLOGIE UND PHYSIKALISCHEN GEOGRAPHIE VON NORDSYRIEN.

Mit Anhang:—(1) Auszug aus dem Tagebuch einer geologischen Studienreise in Nordsyrien, mit Einflechtung vieler geologischen, botanischen, &c. Notizen. (2) Erläuterungen zu der beiden Karten von Nordsyrien. (3) Neue barometrische Höhemnessungen in Syrien.

One Volume of Text in Royal 4to, with 10 Illustrations, and 2 LARGE MAPS of Northern Syria (1 : 500,000), one OROGRAPHICAL (54 : 76 cm.) and one Coloured GEOLOGICAL (54 : 90 cm), with 2 Sections.

Price 36 Marks (£1 16s.).

Sold separately. MAP OF NORTHERN SYRIA (with indication of all the routes; Scale, 1 : 500.000 (54 : 76 cm.); with Explanations (15 pp.). Price 8 Marks (8k).

See Review in NATURE, No. 1127 (June 4, 1891).

Nearly Ready.

DR. A. PHILIPPSON.

DER PELOPONNES.

Versuch einer Landeskunde auf geologischer Grundlage. Nach Ergebnissen eigener Reisen.

One Volume of Text. Royal 8vo, with 40 Sections, 1 large Coloured GEOLOGICAL MAP (15 Colours) in 4 Sections (Scale, 1 : 300,000), and 1 large Coloured TOPOGRAPHICAL MAP (with Mountain-ranges), in 4 Sheets (1 : 300,000).

Price, 45 Marks (£2 5s.).

THE VERTEBRATE FAUNA OF SCOTLAND.

Fourth Volume.

A VERTEBRATE FAUNA of the ORKNEY ISLANDS. By T. E. BUCKLEY, B.A., F.Z.S., and J. A. HARVIE-BROWN, F.R.S.E., F.Z.S. One Volume. Small 4to. Illustrated with Photogravure Plates from Drawings by J. G. MILLAIS, as well as from Photographs taken specially for the Book. Price 30s.

[*Now Ready.*

Third Volume.

THE BIRDS OF IONA AND MULL, and other Natural History Notes, 1852-70. By the late HENRY DAVENPORT GRAHAM, and Edited by J. A. HARVIE-BROWN, F.Z.S., &c. Illustrated from the Authors' Sketch-books. One Volume. Small 4to. Price 21s. net.

"There is a freshness and originality about them which makes them extremely pleasant reading."—*Field.*

"In the seclusion of the 'sacred island,' even now invaded by the tourist for only a brief season, Graham had not merely ample opportunities for studying natural history, but also leisure for thinking. Consequently, the book is full of original suggestions, derivations of words, scraps of folk-ore, &c."—*Athenæum.*

"If Captain Marryat, instead of devoting his time after leaving the service to writing novels, had wandered off to a desolate island and turned wild-fowler and ornithologist, he might well have written such a book as that which the literary executors of the late H. D. Graham have issued under the sober title of 'The Birds of Iona and Mull.'"—*Spectator.*

Second Volume.

A VERTEBRATE FAUNA of the OUTER HEBRIDES. By J. A. HARVIE-BROWN, F.R.S.E., and T. E. BUCKLEY, F.Z.S. One Volume. Small 4to, with Maps and Plates. Only a very few Copies remaining at 63s. net.

"It is rarely, indeed, that a book comes before us which promises so little and gives so much as the delightful volume which Messrs. Harvie-Brown and Buckley have dedicated to the Outer Hebrides."—*Saturday Review.*

Edinburgh: DAVID DOUGLAS, 10 Castle Street.

ZOOLOGICAL SOCIETY'S LATEST PUBLICATIONS.

Proceedings of the General Meetings for Scientific Business of the Zoological Society of London for the year 1891, Part I., containing the Papers read in January and February, with Fourteen Plates. Price 12s.

Transactions of the Society, Vol. XIII., Part 2. Price 21s., containing the following papers:—

Prof. W. K. Parker, F.R.S., on the Morphology of a Reptilian Bird (*Opisthocomus cristatus*), with Four Plates.

Prof. F. Jeffrey Bell, F.Z.S., Contributions to our Knowledge of the Antipatharian Corals, with Two Plates.

These Publications may be obtained at the Society's Office (3 Hanover Square, W.), at Messrs. LONGMANS, the Society's Publishers (Paternoster Row, E.C.), or through any bookseller.

THURSDAY, JULY 2, 1891.

CRYSTALLOGRAPHY.

Elements of Crystallography for Students of Chemistry, Physics, and Mineralogy. By George Huntingdon Williams, Ph.D., Associate Professor in the Johns Hopkins University. Second Edition, Revised, pp. 246, with 383 Woodcuts and 2 Plates. (London: Macmillan and Co., 1890.)

THE position which crystallography ought to occupy in a scheme of scientific education is far from being generally recognized. Every day the importance of this branch of science, not only to the mineralogist and geologist, but also to the physicist and chemist, is becoming more deeply felt; and yet, as a general rule, the systematic study of crystallography is left quite unprovided for in our schools and Universities.

If we take any standard treatise on physics, we shall find that the subject of the measurement and calculation of crystal forms is almost, if not entirely ignored; and though it is, of course, absolutely impossible to discuss optical and other physical phenomena without reference to the wonderfully suggestive relations which exist between the properties resulting from internal molecular structures, and the crystalline forms which are the "outward and visible sign" of such molecular structure, yet the references are usually vague and, not unfrequently, misleading. In confirmation of this statement, it may be mentioned that in a very widely-used treatise on physics—one that has passed through many editions in this and other countries—there is a hopeless confusion between the terms "hemihedrism" and "hemimorphism" in the account which is given of the remarkable phenomena of pyro-electricity.

Nor, as a rule, have chemists dealt more adequately with the subject of crystallography than their brethren the physicists. In many chemical treatises we find such terms as pyramidal, prismatic, octahedral, rhomboidal, &c., employed so loosely as not to give the student the faintest idea of the real symmetry of the forms which are referred to. This neglect of crystallography by chemists is seen to be the more serious when we remember two important circumstances—first, that crystallization is often the only means which chemists possess of isolating and readily distinguishing many bodies; and secondly, that new substances are being continually formed by the chemist, the study of some of which may throw new and important light upon crystallographic principles.

Mr. Fletcher, in a very suggestive address to the Mineralogical Society, has justly remarked:—

"Hitherto, at least, the chemists of this country have been too content, either to leave the crystalline forms of their artificial products undetermined, or to impose the task of their determination on the already sufficiently occupied mineralogist. It seems obvious that in a satisfactory system of education every chemist should be taught how to measure and describe the crystalline characters of the products which it is his fate to call into existence. . . . A knowledge of the elements of crystallography, including the mechanics of crystal-measurement, ought to be made a *sine quâ non* for a degree in chemistry at every University."

The consequence of this neglect of crystallography by physicists and chemists has been that the teaching of crystallography has fallen almost entirely into the hands of mineralogists and geologists. But there is no more reason why every book on mineralogy should commence with a crystallographic treatise, than that it should include dissertations on refraction or articles on chemical analysis. "Crystallography should be taught as a special subject," and the student who, after his training in physics and chemistry, takes up the subject of mineralogy, ought to know at least as much of the measurement and symmetry of crystal forms, as he does of the effects of various media on different kinds of radiant energy, or the reactions of the several bases and acids.

It would be easy to show that, much as mineralogists have done for the study of crystallography, the latter science would have been developed more logically, and perhaps more rapidly, if the illustrations of the phenomena of crystallization had not been so exclusively sought among natural products. We find not a few examples in the terminology of the science of the effects of this one-sided growth of crystallography.

Crystallography is based upon purely mathematical considerations, and the study of the principles of crystal-measurement, the discussion of crystal-symmetry, and the calculation of fundamental forms, ought clearly to be one of the first branches of applied mathematics to be taken up by the student of physics; thus the study of crystallography should certainly precede that of physical optics. If this course were followed, the student of chemistry and mineralogy would come to the teachers of those sciences with such an amount of preliminary information as would enable him to profit by their instructions.

In the work now before us, Dr. Williams fully recognizes the importance of the principles for which we have been contending, and has endeavoured to supply English-speaking students with a short and clear treatise on the principles of crystallographic science. It is certainly remarkable that the countrymen of Wollaston, Whewell, and Miller should have had to wait so long for a work of this character; though every student of the subject must gratefully remember the aid afforded by the admirable little primer prepared some years ago by Mr. Gurney, and published by the Society for Promoting Christian Knowledge.

Of Dr. Williams's qualifications for undertaking a work of this kind it is unnecessary to speak. His numerous original researches afford abundant evidence of his devotion to crystallographic study, and in the preparation of the work he has had the advice and assistance of one of the first crystallographers of the United States, Prof. S. L. Penfield, of New Haven.

In order to keep the work within the smallest possible limits, it has been restricted to geometrical crystallography, but otherwise the work has been modelled upon the same lines as Groth's standard work, "Physikalische Krystallographie." The plates and very numerous woodcuts afford the greatest possible aid to the reader, and the typography leaves nothing to be desired. In looking through this revised edition, we are struck with the almost entire absence of those typographical errors that so easily creep into a work of this kind, and which,

Digitized by Google

though so obvious to an expert, often prove to be a source of infinite trouble to the beginner.

In dealing with the vexed question of crystallographic notation, we think Dr. Williams has exercised a very wise discretion. The simple and easily understood symbols of Naumann have been employed in the first instance, but in almost every case the corresponding symbol of Miller's system has been added in brackets. While all students of physics, chemistry, mineralogy, and geology ought to equip themselves with such an amount of crystallographic knowledge as may be derived from the study of this book, only a very small proportion of them are likely to be called upon to deal with the higher and more complicated problems of the science. The small minority of students who devote themselves to purely crystallographic researches may be fairly recommended to employ from the first the beautiful method of notation devised by Whewell and perfected by Miller; but it is more than doubtful if the student with a smaller amount of mathematical training would gain any real benefit from such a course. In an appendix, "on zones, projection, and the construction of crystal figures," the author of this work has indicated to such a beginner the nature of some of the methods of investigation which are pursued by more advanced students.

In any future edition of the work—and such, we feel sure, will certainly be called for—we think that the author would do wisely to add a table showing the symbols of the chief forms according to all the different systems of notation commonly employed. The student who turns to the classical memoirs of Des Cloizeaux, Mallard, Bertrand, and others of the French school of crystallography, would thus be enabled to avail himself of much valuable literature, which, owing to the employment of an unfamiliar notation, must otherwise remain a sealed book to him.

We have spoken regretfully at the outset of this notice of the general neglect of crystallographical studies; but we are compelled to admit that, for this neglect, crystallographers themselves are largely to blame. The confusion produced by numerous rival systems of notation is answerable for much of that feeling of despair among those who attempt to make themselves acquainted with the subject. If the time has not yet arrived when a uniform crystallographic language can be agreed upon, much might be accomplished if the plan adopted by the author of this work of giving in every case the symbols according to *two* systems were followed. This is already done in the *Zeitschrift für Krystallographie*, the *Neues Jahrbuch für Mineralogie*, &c., the Journals of the English and French Mineralogical Societies, and several other well-known periodicals. If a conference of the leading crystallographers of Germany, France, and England could be held to decide upon the order in which the axes should be taken in writing symbols and other similar arrangements which are purely conventional and arbitrary, we might hope to see much of the confusion removed that has so long been a bar to the progress of this most fascinating and important branch of science.

We feel assured that the simultaneous publication in this country and in America of so simple and at the same time so accurate a text-book of the subject as the work we are now considering will do much towards reviving and diffusing a taste for the study of crystallography The student who masters the contents of this little book will undoubtedly have much more to learn before he is competent to deal with all the higher problems of crystallographic science; but, however far his researches may be carried in the future—and this is, perhaps, the very highest praise we can give to the book—he will certainly have little, if anything, to *un*learn.

JOHN W. JUDD.

PHOTOGRAPHY IN COLOURS.

Photographie des Couleurs par la Méthode Interférentielle de M. Lippmann. By Alphonse Berget. (Paris: Gauthier-Villars et Fils, 1891.)

THIS interesting little *brochure* contains an account of the recent achievements in colour photography which have been made so widely known to the English public through the daily papers. Coming from the pen of an "attaché au Laboratoire des Recherches (Physique) de la Sorbonne," we may take this contribution as an authorized exposition of M. Lippmann's work, and as such it will be found useful by physicists, chemists, and photographers, as well as by the general reader who wishes to know the real state of the case concerning this important departure in photographic methods. In a short historical introduction the author calls attention to the previous photochromatic attempts by Seebeck in 1810, by Herschel in 1841, by Edmond Becquerel in 1848, by Niepce de St. Victor in 1851 to 1866, and by Poitevin in 1865. It is stated that these and all similar attempts were based upon purely chemical methods, the investigators seeking for some sensitive compound which would give chromatic impressions corresponding to the colours impinging on the film. M. Berget adds the important remark: "*a priori*, ce problème est irréalisable."

Chapters ii. to v. are devoted to elementary optical principles. Chapter ii. deals with vibratory movements and their propagation, wave-length and period, and sonorous waves. In the third chapter the phenomenon of interference is described and explained; in the fourth chapter we have sections on the luminiferous ether, the velocity of light, the decomposition of white light by a prism, and Fresnel's theory of the spectrum colours. The subject of complex colours, as distinguished from the pure colours of the spectrum, is also dealt with in this chapter, and is of special importance in connection with the colours of natural objects, to which the author devotes a short section. It is pointed out that the principle of superposition of vibrations holds good in optics as in acoustics, and that just in the same way that the diaphragm of a phonograph can take up and faithfully transmit the extremely complex system of superimposed aërial vibrations produced by the human voice, so the ether transmits the complex superimposed vibrations emanating from coloured objects. In connection with the history of the undulatory theory, the whole credit is given to Fresnel: "L'honneur de donner la première théorie rationelle de la lumière, en la considérant comme résultat d'un mouvement ondulatoire, était réservé à un savant français: Fresnel." We should like to have seen Thomas Young receive at least an honourable mention.

Digitized by Google

The subject of interference receives more detailed treatment in chapter v., the interference of direct and reflected waves, and the theory of Newton's rings, being specially dealt with. It is not till we come to the sixth chapter that we are introduced to the main subject of the *brochure*. The principle which guided M. Lippmann in his experiments is well and tersely given. Imagine a plane metallic mirror with its reflecting surface coated with a transparent, homogeneous film of a silver haloid in albumin or collodion. Supposing a coloured ray of definite wave-length to fall on such a film, the undulations would traverse the transparent sensitive film, and being reflected from the polished surface of the mirror, and meeting the incident waves, would produce interference. The space in front of the mirror would thus be occupied by parallel planes alternately light and dark, and separated by half wave-lengths, *i.e.* by spaces of 1/4,000,000 of a millimetre. There is therefore ample space, even within the thickness of the film, for several of these planes of interference. On development, the planes corresponding to the light intervals would alone give films of metallic silver, while the dark intervals would remain unaffected. On fixing, there would thus be left in the film a series of parallel films of metallic silver separated by half wave-lengths. Any pair of such films constitute a thin plate in the Newtonian sense, and will give by interference a colour corresponding to that which produced the original deposition of the films when viewed by reflected light.

To realize the foregoing principle experimentally, M. Lippmann has found it necessary to use dry films of collodion, or albumin, or gelatine sensitized by immersion, as in the old wet collodion process: emulsions are granular and opaque, and contain particles which are gross in comparison with the half wave-length of a spectrum colour, and cannot be used. Moreover, it has not been found practicable to coat the reflecting surface of the mirror directly with the sensitive film, because the free iodine tarnishes the silver and destroys its reflecting power. This difficulty has been surmounted by making the coated glass plate one side of a shallow trough with parallel sides filled with mercury, the coated side being inwards, and in close contact with the mercury. The conditions for reflection and interference are thus fulfilled. The image of the spectrum is focussed on a glass plate with a ground surface, which is temporarily fixed to the side of the cell or trough in the same position as that occupied by the sensitive plate, *i.e.* with the ground surface inwards. After focussing, the ground glass is removed, and the sensitive plate substituted for it in the position described.

The spectrum was produced by an electric arc light of 800 candle-power, and the time of exposure for the different parts of the spectrum was regulated by interposing cells with coloured solutions, beginning with a solution of helianthin which transmits only the red and yellow, then replacing this by a cell of potassium dichromate which transmits the red, yellow, and green, and then finally exposing for a few seconds without any screen, so as to impress the blue and violet. The whole time of exposure varies, according to the sensitiveness of the film, from half an hour to two hours. The details of development and fixing are given by M. Berget, and do not differ fundamentally from the ordinary methods. The finished image, *when dry*, shows the spectrum colours by reflected light with metallic brilliancy, and as the colours are purely optical, depending only on reflection and interference, they are permanent. As the author points out, it is certainly a marvellous tribute to the fidelity of the photographic method that a series of laminæ of metallic silver separated by intervals of only about 1/4,000,000 of a millimetre should retain their positions with optical accuracy during the processes of fixing and development.

There can be no doubt—as will be admitted by all who have seen the results—that M. Lippmann is to be congratulated on having made a most important advance in the methods of photochromy. How far his experiments go towards the realization of the great problem of photographing objects in their natural colours is a question quite distinct from his present achievement. M. Berget tells us that satisfactory reproductions of coloured glasses illuminated from behind by the electric light have been obtained, but this is only a very little step in the desired direction.

"Que reste-t-il à faire pour rendre *absolument usuel* le procédé photochromique de M. Lippmann?" There remains a great deal! Not the least of the requirements is a transparent sensitive film equally sensitive to every colour of the spectrum, and sufficiently sensitive as a whole to enable the impression to be secured with a moderate exposure, instead of 30 to 120 minutes. Till this is accomplished we are not much nearer the solution of the problem of photography in natural colours than we were before. M. Berget speaks hopefully of the prospects in this direction, and we wish every success to his anticipations. But it is no detraction from the merit of M. Lippmann's results if these have no immediate bearing on practical photographic processes. As a triumph of physical science these experiments will live.

"C'est aussi un triomphe pour la science française, car ce mode de reproduction des couleurs du spectre à l'aide des lames minces limitées par des plans d'argent constitue une matérialisation, réalisée par un savant français, de ces ondes lumineuses conçue pour le première fois par le puissant génie d'un autre Français illustre: j'ai nommé Augustin Fresnel."

With this patriotic outburst M. Berget concludes his pamphlet, and the compatriots of Niepce and Daguerre may well be gratified with this latest emanation from the physical laboratory of the Sorbonne.

R. MELDOLA.

OUR BOOK SHELF.

Geometry of Position. By R. H. Graham, Author of "Graphic and Analytic Statics." (London and New York: Macmillan and Co., 1891.)

THIS work essays to fill an existing want by providing an English text-book on the important subject of geometry of position in relation to graphical statics.

The author gives an introductory chapter on anharmonic pencils and ratios, followed by an interesting chapter on projective conics, and devotes the remainder of the book to the application of graphic methods to statical problems, including, amongst others, the discussion of Maxwell's theory of reciprocal figures.

The chapter on anharmonic pencils and ratios would have been considerably improved by the introduction, at the beginning, of more definitions and explanations of the

Digitized by Google

nomenclature adopted. The proofs of Desargue's theorem and its converse, given on p. 3, are unduly compressed, considering the early stage at which they are introduced; and the student's preliminary difficulties will be increased by the fact that the enunciations have been given in succession, while there is nothing to indicate which is to be treated first.

In the chapter on reciprocal figures, we would suggest that the proof given of Theorem I., Art. 50, might with advantage have been dispensed with. In Art. 52 it is erroneously assumed that OB' is equal to force (1); this assumption mars a proof which would be otherwise good.

The work exhibits evidence of originality, and it is, perhaps, to be regretted that the proof-sheets have apparently been revised only by the author himself. Their revision by one who had no part in compiling them would probably have contributed to a better arrangement, and to the exclusion of much that is vague.

The carefully drawn diagrams of different problems contained in the book form admirable illustrations to the non-technical reader of the nature of the operations involved in the application of the graphical calculus, and of the character of the results obtained by it. They are the more welcome as such information is not readily available in English text-books, while in foreign treatises it is often developed in such minute detail as to make the foundations nearly inaccessible to the general reader.

A word of praise is due to the interesting collections of examples at the ends of the chapters, which are, it seems, mostly original, but partly drawn from sources not often laid under contribution in the ordinary text-books.

ALEX. LARMOR.

The Species of Epilobium occurring North of Mexico. By Dr. Trelease, Director of the Missouri Botanic Garden. From the Second Annual Report of the Garden, issued April 1891. 48 pages, 48 plates.

EPILOBIUM is not a very large genus, but is spread universally through the north temperate zone, both amongst the plains and mountains, and reappears in plenty in New Zealand. The species are very difficult of delimitation and definition, and great diversity of opinion has prevailed as to their number, and the validity of the characters which have been used to characterize species. It is evident, moreover, that many of them hybridize freely in nature. Passing over the earlier well-known writers, such as Pursh, Muhlenberg, Hooker, and Gray, in 1876 Barbey contributed a monograph of the Californian species to Brewer, Watson, and Gray's "Flora of California," and later published excellent figures of the new species which he there described. In 1884, Haussknecht published a monograph of the whole genus. Of the 38 species dealt with in Dr. Trelease's paper, 13 have been proposed by Haussknecht, 3 by Barbey, 4 by himself, and one by Parish, so that more than half the 38 have been lately described for the first time. Dr. Trelease describes fully all the species known in Temperate North America, gives an octavo plate of each of them, and a detailed account of their geographical distribution, citing the numbers of all the recent collectors. Of the 38 species only 9 extend their range beyond the American continent. The paper will be a very acceptable contribution to our knowledge of a difficult genus, and will no doubt be incorporated in the new "Flora of North America," of which the second volume is already published, and the first and third of which we anxiously wait for.

J. G. B.

A Guide Book to Books. Edited by E. B. Sargant and Bernhard Wishaw. (London: Henry Frowde, 1891.)

THERE are so many books of all kinds that ordinary readers may be excused if they are sometimes at a loss as to the works which they ought to select for study. The editors of the present volume have come to the aid of such readers, and may be congratulated on the manner in which they have accomplished a useful but most troublesome task. They make no attempt, in a philosophical sense, to classify the various subjects with which authors have dealt; they simply take these subjects one after the other, in alphabetical order, and set down what seem to them the best books relating to each. Taking into account the amount of space at their disposal, they probably could not have chosen a plan that would have been more readily intelligible. Of course opinions will differ about the value of the works included in the several lists. Everyone who consults the volume will be of opinion that the editors have omitted some things which they ought to have noted, and that they have noted some things which they ought to have omitted. But there cannot but be a general agreement that, upon the whole, the selection has been made on sound principles, and that it is likely to be of real service to very many of those who may have occasion to refer to it. A large number of eminent writers have helped the editors, not only by drawing up lists of books, but by giving them much valuable advice.

Tasmanian Official Record, 1891. By R. M. Johnston, F.L.S. By Authority. Second Year of Issue. (Tasmania: William T. Strutt, Government Printer, Hobart, 1891.)

ANYONE who may wish to obtain information about Tasmania will be hard to please if he does not find what he wants in this elaborate volume. It begins with an account of the general physical outline of the island, and then we come to Tasmanian history, and to the Tasmanian constitution and government. After a chapter on Crown lands we are invited to consider the geology and mineral products of Tasmania, its flora and vegetable products, fauna and animal products, population, vital statistics, trade and interchange, accumulation, finance, production, law, crime, and protection, and "intellectual and social provision." The work is wound up with a view of the progress of Australasia, and a summary of general statistics. In the present issue some important additions have been made to the book as originally published, and by devoting attention to classification the editor has tried to "obviate any difficulties that might arise from the necessity of bringing together in one volume such a variety of subjects."

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Albert University.

PROF. LANKESTER, in the interesting letter published in NATURE for May 28 last (p. 76), expresses his desire to have "a genuine professorial University set on foot in London, not because it is London, but because University and King's Colleges are there, and respectfully petition Her Majesty to do for them what the monarch has done in past days for other Universities."

I have not seen the petition of the Colleges. But I have before me the draft charter adopted by their Councils, which I presume is intended to give effect to the prayer of the petition. I can hardly imagine that Prof. Lankester was acquainted with its contents when he penned the sentence which I have quoted.

If the Albert University is called into existence—and it seems very probable that its charter will be granted—it will be an institution very similar to what the University of London was in the early years of its existence, when it drew its candidates only from the so-called affiliated Colleges.

The charter commences by reciting "that it is expedient there should be constituted in and for the London district (defined as

Digitized by Google

'a radius of fifteen miles from Somerset House') a University . . . commending to its students systematic courses of teaching and methods of study." But "commending" is what we all do now.

The new University is to be of the federal type. Beginning with University and King's, "other Colleges may from time to time be admitted." This was inevitable, though my pointing out the fact made my friend Prof. Lankester somewhat angry.

Any medical school may be admitted which is recognized as efficient by any qualifying body under the Medical Acts. But while Colleges will have representatives on the Council, the medical schools will only have representatives on the Faculties.

Degrees may be granted apparently in any subject the Council please, subject to a regular course of study and examination. This will apparently admit theology, which is probably a desirable thing, provided it be unsectarian.

The powers to grant degrees are rather large, and deserve careful consideration. The London radius at once, as has been the case with the existing University, goes off into Imperial infinity in the provision that anyone who has been a resident student in any University in the Empire may count his time and examinations, except that a "final portion of the period of study" and the "final examination" shall be passed in the University.

There is an unlimited power to grant *ad eundem* degrees as well as honorary degrees at the discretion of the Council. Fellows of University and King's Colleges (a purely honorary distinction in itself) are indicated as fitting recipients, and also "past students of the said Colleges," a rather large door to open if in the future a degree is to have any meaning at all.

Power is taken to examine into the efficiency of schools or any academic institutions—work already in the hands of other Universities—and apparently the London radius again becomes infinite.

Independent University lecturers may be appointed.

The Council will consist of members appointed for five years by (1) the Crown (Lord President); (2) Convocation; (3) Colleges; (4) Colleges of Physicians and Surgeons; (5) Faculties. The Faculties are to be constituted (1) of teachers in the Colleges; (2) of examiners; (3) of persons who are or have been engaged in University teaching in London. The Boards of Studies are delegations from the Faculties, as they should be. All this is much on the lines sketched out in my own letter in NATURE.

A rather remarkable feature in the scheme is the creation of a Convocation of graduates. Whatever may be the function of this body in other Universities, it is somewhat surprising to meet with its existence in what professes to be a teaching University.

The examinations are to be conducted by examiners who are members of the respective faculties associated with external examiners; the teacher-examiner seems not to be insisted upon.

These are the essential elements of the proposed constitution. If it is asked what distinctive character the Albert University will possess which will mark it off from the existing University, or from that body as it might be conceivably reconstituted, I must confess that it seems to me to lie in a very small compass. Notwithstanding the use of the ambiguous word "commending," when one would have expected "prescribing," I take it for granted that the essential feature in the whole scheme is the enforcement upon candidates for degrees of attendance upon a curriculum. But in the existing University, this is already required in the Faculty of Medicine. Prof. Huxley has further urged it in the Faculty of Science; and for my part I believe that the time has arrived when it might be demanded without difficulty. The prominence given to practical work in the science examinations has made it all but impossible for a candidate to acquit himself successfully who has not attended a competent course of instruction. To insist upon a curriculum would be now scarcely more than the practical recognition of this fact. The only real point of divergence is in the Faculty of Arts; about this I speak with some hesitation. It may be that the enforcement of a curriculum is desirable; I am not satisfied that in this faculty it is so, or at any rate absolutely essential, as I think it is in the Faculty of Science. With this exception I can see no net public gain in the new scheme to justify the creation of the cumbrous machinery of a new federal University.

Seeing that the existing University is a State institution in actual possession of the field, I think the public at large might have reasonably expected from the Senate some statesmanlike criticism, rising above the petty level of supposed self-interest in the very serious action which the Government is apparently about to take.

They content themselves, however, with a sort of half-sulky acquiescence in the scheme "so far as it proposes to confer on the petitioning Colleges the power of granting degrees in arts and science to students of the Colleges who have pursued their entire academic curriculum within the Colleges." The Senate, a little maliciously, proceeds to point out that "the petition of the Colleges lays great stress upon the paramount importance of close association of students and teacher-examiners, and of placing the power of granting degrees in the hands of those teachers who have instructed the candidates." It not unnaturally insists upon the inconsistency with this position of the proposal "to accept residence and examinations at other Universities," if only a final period of study, "which might be a short attendance at evening classes," be passed at the new University.

It also objects to the honorary and *ad eundem* degrees. But its criticism is even more destructive in regard to the Medical Schools. It is quite obvious that if the Medical Schools joined the Albert University, the teacher-examiner system would disappear, and the new and the old Universities would be simply competing agencies for doing the same kind of work in the same kind of way. The same argument applies more or less to the other faculties as soon as the number of constituent Colleges becomes numerous.

Yet so great is the magic of a phrase that the daily papers in reporting the proceedings in the Privy Council describe the scheme as that of a Teaching University. A University of the Scotch or German type may have some claim to that title; but no federal University can ever possess a valid one, for the simple reason that there will always be a morphological distinction between the Colleges which teach and the University which examines and grants degrees.

Prof. Lankester contended in his letter that the question whether University and King's Colleges should have a University Charter was a sort of private affair between them and the Government. But I do not think this view can be accepted. Whether we like degrees or whether we do not, they have a certain value in the eyes of the public. Personally, I have no objection to the multiplication of Universities, if each has a proper geographical area assigned to it. But the multiplication of Universities in the same place seems to me a great evil. It cannot be assented to without the necessity being shown to be overwhelming. And in the present case it appears to me that it cannot be so shown. If the existing University is so injurious to the best interests of the higher education that another is imperatively demanded to do the work in which it fails, then it appears to me that two obvious points present themselves:—

(1) The new University should be free from the defects that attach to the old one. Prof. Lankester speaks of the "thraldom" of "the Imperial centralizing institution"; but when the matter comes to be looked into, the new institution also proposes to be Imperial and centralizing, and will be found to exercise the same or even greater thraldom on the individual teacher.

(2) If the old University is really doing mischief, it is the paramount duty of the supreme Government, whose creature it is, to reform it. The fact that the Senate and Convocation are at loggerheads how this is to be effected is really beside the question. When public opinion demanded the reform of the older Universities, new ones were not created alongside the unreformed old ones; but a Commission with executive powers effected the changes which were necessary. And for a similar procedure there is still time at Burlington Gardens.

The Holarctic Region.

REVIEWING the recently-published "Introduction to the Study of Mammals" by Prof. Flower and Mr. Lydekker, Prof. Lankester states (*suprà*, p. 122) that "The authors of the present work mention Dr. Heilprin's opinion that the Palæarctic and Nearctic regions should be united and called the Holarctic region. But they do not adopt this opinion, nor refer to Huxley's proposal to term this same area Arctogæa," and so on. Now, in this last statement my good friend the reviewer, perhaps writing from memory, is mistaken. Had Prof. Huxley proposed to limit his "Arctogæa" to the Palæarctic and

Digitized by Google

Nearctic regions of Mr. Sclater and Mr. Wallace, I should certainly not have suggested to Prof. Heilprin a new name for that combination. Anyone looking to the passage (Proc. Zool. Soc., 1868, pp. 314, 315) in which Prof. Huxley defined his "Arctogæa"—a name to which, let me say, I have not the least objection—will see that it signifies that part of the world which is not "Notogæa," and therefore includes the Ethiopian and Indian regions of Mr. Sclater, whereas my "Holarctic" region expressly excludes them, and is therefore a very different thing from "Arctogæa" in its true sense.

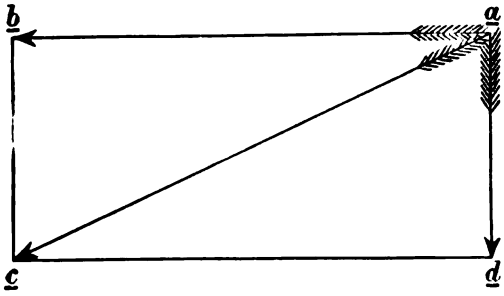
Force and Determinism.

IN your issue of March 12 (vol. xliii. p. 491), Dr. Oliver J. Lodge characterizes as "perfectly correct" the statement "that, although expenditure of energy is needed to increase the speed of matter, none is needed to alter its direction." I have looked in vain for some notice of this apparently strange doctrine in your subsequent issues, with the exception that Prof. C. Lloyd Morgan (April 16, p. 558) objects that the direction of motion cannot be changed by purely metaphysical means, or will-power. But passing over this rather important and interesting point with only the observation that Sir John Herschel thought differently—thought, in fact, that "without the power to make *some* material disposition, to originate *some* movement, or to change, at least temporarily, the amount of dynamical force appropriate to one or more material molecules, the mechanical results of human or animal volition are inconceivable" (*Fortnightly Review*, July 1, 1865, vol. i. p. 439)—I desire to call a moment's attention to the first statement alluded to.

Dr. Lodge admits that "expenditure of energy is needed to increase the speed of matter." But, as a matter of fact, is it not very difficult, if not indeed practically impossible, to change the direction of a moving body without affecting its speed? "A force at right angles to motion does no work," says Dr. Lodge. Let us examine this statement for a moment. Let a body be moving in the direction *a* to *b* with a speed sufficient to traverse the distance in one unit of time. Then let a force be applied to



the body at *a*, at right angles to the direction of its motion, sufficient, if acting alone, to carry the body to *d* in the same unit of time. By the composition of forces, the body, at the end of the unit of time, would, therefore, be found at *c*. But the distance *ac* is greater than *ab*; and as, by the interposition of a force at right angles to its motion, the body has thus traversed a greater distance in the same time, has not its speed, as a matter of fact, been increased? and is not this increase of speed actual work? and does not this work require actual energy to perform it?

EVAN MCLENNAN.

Brooklyn, Iowa, U.S.A., June 9.

I AM glad to see my statement called in question, and hoped that it would have aroused more antagonism than has yet been expressed; because I do believe that it has important psychological or metaphysical consequences, and should therefore either be repudiated by physicists or after due discussion be accepted by non-physicists.

With regard to the special objection raised by Mr. McLennan, it may be sufficient to remark that, in his diagram, *ac* is the line of motion, *ad* the direction of the force, and that *ad* is not at right angles to *ac*. His difficulty seems to be the one that some people always feel with regard to the use of infinitesimals in general. He must remember that his diagram will not apply to the case of curvilinear motion unless the impulses contemplated are momentary and infinitesimal.

OLIVER J. LODGE.

The Scorpions at the Zoo.

YOUR contributor of the notice, published in NATURE on June 18 (p. 163), on the contents of the Insect-house at the Zoo, who laments the unfortunate circumstance that the scorpions there in captivity remain unnamed, may be glad to learn that these creatures may be easily identified, and, with a little dexterity, fearlessly handled.

During a recent visit to this house, the keeper obligingly showed me the two Egyptian scorpions, one of which—the black individual with the thick tail—was easily recognizable as *Prionurus crassicauda*, Oliv., a tolerably common North African and Syrian form.

To the other, however, I could not so readily assign a name; partly owing to its partial concealment, and partly to the fact that critical inspection is required to distinguish between the species of the genus to which it belongs. It appeared, nevertheless, to be a specimen of *Buthus europæus*, Linn., the commonest of all the Mediterranean scorpions. But my attempt to verify this point by closer examination was immediately frustrated by the keeper; who, evidently thinking that I was qualifying for incarceration in Bedlam, hastily interposed when I stretched out my hand to pick up the noxious animal.

The third scorpion I did not see; but doubtless it is a specimen of one of the species of *Euscorpius*. This, too, can be easily named, no doubt; but it will be necessary to handle the specimen in order to be certain on the point.

I would warn your contributor not to be too sanguine of the permanence of the amicable relations that appear at present to be established between these three Arthropods. If the supply of dead mice runs short, there will, of a surety, soon remain nothing but a few fragments of *Euscorpius*. Such thoroughgoing cannibals are not likely to be squeamish, when a member of another genus is before them.

In conclusion, some of your readers may be interested to know that the spider referred to as *Lycosa portosantana*—which, by the way, should be styled *Tarantula maderiana*—is a very near ally of the famous and historical Tarantula of Italy; and that the hairy Brazilian monster, the so-called Mygale, who squats under a broken flower-pot in the next cage, has no more claim to the title Tarantula than any other Arachnoid with a formidable aspect.

Cetaceans in African Lakes.

WITH reference to Mr. Sclater's inquiry (NATURE, June 11, p. 124) as to the occurrence of porpoises in the Victoria Nyanza, the following extract from Bernier, who wrote about 230 years ago, will probably prove of interest.

I may add that in another passage Bernier gives further information regarding the sources of the Nile.

It would seem from the passage quoted that the occurrence of a Cetacean in the Abyssinian sources of the Nile was probably known to early travellers, and, like the occurrence of diamonds in other parts of Africa, cannot be regarded as a new discovery.

Science and Art Museum, Dublin, June 22. V. BALL.

An Armenian named Murat and a Mogul who came as ambassadors from the Christian King of Ethiopia (*i.e.* Abyssinia) to Aurungzeb shortly after his accession to the Mogul Empire, in 1659, told the French physician Bernier, who then resided at the Mogul's court, "that the Nile had its origin in the country of *Agaus*, that it issued out of the earth by two springs bubbling up near to one another, which did form a little lake of about 30 or 40 paces long; that, coming out of this lake, it did make a considerable river; and from space to space it received small rivers increasing it. They added that it went on circling and making as 'twere a great isle, and that afterwards it tumbled down from steep rocks into a great lake in which there were divers fruitful isles, store of crocodiles, and (*which would be remarkable enough if true*) *abundance of sea calves, that have no other vent, &c., than that by which they take in their food*, this lake being in the country of Dambea, three small days' journey from Gundar and four or five days' journey from the source of the Nile, &c., &c." ("The History of the Empire of the Mogul," English translation of 1684, p. 44).

ON SOME POINTS IN THE EARLY HISTORY OF ASTRONOMY.[1]

V.

IT is imperative to be perfectly definite and clear on the question of the amplitudes above 26° at Thebes. Any amplitude within 26° means that up to that point the sun at sunrise or sunset could be observed some day or days of the year—once only in the year if the amplitude is exactly at the maximum, twice if the maximum is not reached. But in the case of these temples with greater amplitudes than 26°, it is quite clear that they can have had nothing to do with the sun. Is there, then, any additional line of evidence that the Egyptians used these temples to observe the stars? Here a very interesting question comes in; a temple built at one period to observe a star could not go on for ever serving its purpose, for the reason that the declination of the star must change by precession. Therefore a temple built with a particular amplitude to observe a particular star, useful for one period would be useless for another.

We have here possibly a means of testing whether or not any of these temples were used to observe the stars. In those very early days, 3000 or 4000 years B.C., we must assume that the people who observed the stars had not the slightest idea of these possible precessional changes; they imagined, that they were just as safe in directing a temple to a star as they were in directing a temple to the sun But with a star changing its declination in an average way, the *same* temple could not be used to observe the same star for more than 200 or 300 years; so that at the end of that time, if they still wished to observe that particular star, they must either change the axis of the old temple, or build a new one.

As a matter of fact, we find that the axes of the temples have been changed and have been freely changed; that there has been a great deal of work done on many of these temples which are not oriented to the sun, in order to give them a twist.

Once a solar temple a solar temple for thousands of years; once a star temple only *that* star temple for something like 300 years, so that the conditions were entirely changed.

We get cases in which the axis of a temple has had its direction changed, and others in which, where it has been difficult or impossible to make the change in a temple, the change of amplitude has been met by putting up a new temple altogether. We are justified in considering such temples as a series in which instead of changing the orientation of a pre-existing temple, a new temple has been built to meet the new condition of things. That, I think, is a suggestion which we are justified in making to Egyptologists on astronomical grounds.

We cannot, of course, make it with absolute certainty, for the reason that in the case of most of these temples the best Egyptologists cannot give us the most precious piece of information which we require from the astronomical point of view. That is the date of the *foundation* of the temple. If in the case of these temples it were absolutely certain that each temple was built at a certain time with a certain orientation, the use of the precessional globe would tell us at once whether or not that temple was pointed to any particular star. Some other astronomical considerations may here come to our help. If the north polar distance of a star is increasing—that is, if it is increasing its distance from the north pole—its declination is being reduced, and the orientation of the temple would be gradually becoming more and more parallel to the equator; if the declination of the star be increasing, then the orientation of the temple would have had to be more and more north or south. The change in the orientation, therefore, could give us important information, and ultimately we might be able to determine what the name of that particular star was. At present the matter must remain more or less as a suggestion; but if anything like approximate dates can be given, then astronomy really may come to the rescue of the Egyptologist and archæologist generally, and repay that debt to which I have referred, which she owes to so many other sciences.

Although, however, these matters can be discussed in a way that will indicate that the inquiry is raised, I do not wish for one moment to speak of it as being settled, because the observations which have been made already in Egypt with regard to the orientation of these temples have not been made from such a very special point of view; and further some alteration in the amplitude would be made by the presence of even a low range of hills miles away from Thebes in the case of a star rising or setting pretty nearly north or south. No

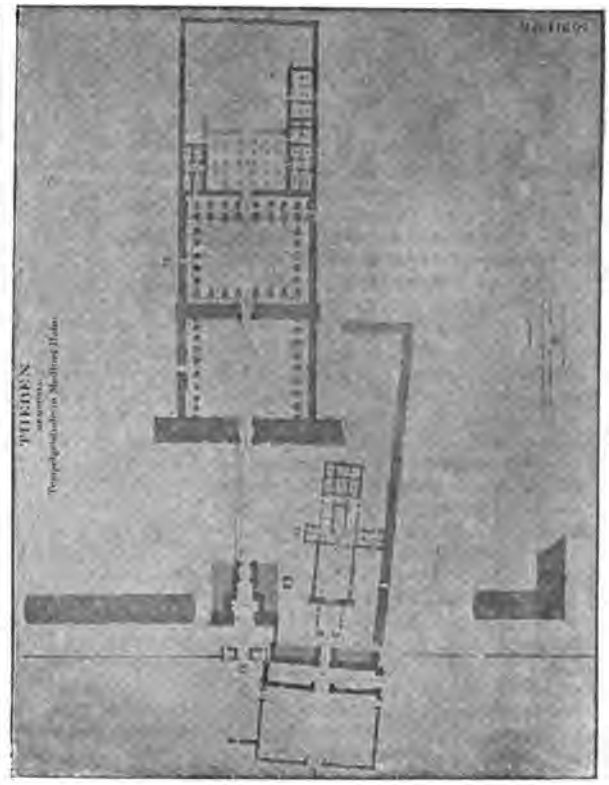

FIG. 14.—The two temples at Medinet Abou, showing the change in their orientation.

one would care to make the assertion with absolute definiteness until it was known whether or not the horizon in each case was interfered with by hills or any intervening objects—was or was not one, in fact, which might be regarded as a sea horizon from the point of observation; if there were impediments, the angular height of them must, of course, be exactly known.

To continue this observation and this kind of thought a little further, we will go back to Karnak generally. In the first place we have the magnificent solar temple.

Next we have two parallel temples, one of them a late addition to the solar temple itself, and another one parallel to it, each of them with an amplitude of 63°, one N. of E., the other S. of W. We have then two parallel temples *at right angles* to the solar temple at Karnak. We have also a temple, with an azimuth of 68° N. of E., and one, probably older still, with an ampli-

[1] Continued from p. 180.

Digitized by Google

tude of 70° or 71° N. of E.; both these temples face northerly, and nearly in the same direction. Near the last temple we have the ruins of another one at right angles to it, and this points to the westward amplitude 19° N. of W. We may assume from the plan of the ruins that the Naos is at the east end of the temple, therefore the chief pylon would have been to the west, and therefore the axis will be in that direction. In the row of sphinxes, a double row connecting the temples of Maut and Karnak, the line is absolutely complete as far as their bases are concerned, with the exception of two where there is a gap, and that gap is exactly in the axis of this temple prolonged. Here is another instance of the rights of the line of sight of a temple being strictly preserved.

The Egyptians have been accused of hating every regular figure, and even in the boundary walls of the temple of Ammon there are two obtuse angles. Round the Maut temple we also have walls, and there again this hatred of similarity seems to come out, for we have one obtuse and one acute angle. But if we examine the thing a little carefully, we find that there is a good deal of method in this apparent irregularity. The wall of the temple of Ammon is parallel to the face of the temple or at right angles to its length. One wall of Maut is perfectly parallel to the face of the temple or at right angles to the sphinxes. And the reason that we do not get right angles at one end of the wall is that the walls of the temple at Maut are parallel to the chief wall of the temple of Ammon. Surely it must be that, before these walls were built, it was understood that there was a combined worship, that they stood or fell together. One thing was not attempted in one temple and another thing in another, but the worship of each was reflected in the other. And if this be true you see that there was no hatred of symmetry, but a definite reason why these walls should be built as they were.

We can depend, and no doubt depend very completely indeed upon the labours of the Egyptologists, in the case of the temples of Rameses and of Khons. No Egyptologist so far, I believe, has ventured to tell us the date of the foundation of Karnak, but what Egyptologists have stated is that those two temples were built by the same king; their architecture is exactly similar, they are parallel to each other, and they altogether bear reference to apparently the same period of Egyptian history. Now that king was Rameses III., and the year according to Brugsch was 1200 B.C. Here then we have a definite basis of work. There is a temple with an amplitude of 63° N. of E., built 1200 B.C.; there is a temple with an amplitude of 63° S. of W., built 1200 B.C. From these amplitudes we determine as before the declinations; they come out 53° N. and 53° S.

Was there an important star with a declination of 53° N., was there another with a declination of 53° S. in the year 1200 B.C.? There *were* two important stars, one with a declination of 53° N. and another of 53° S. at that time. The north star was γ Draconis, the south star was Canopus. This strengthens the view that there was really some astronomical object in the plan and direction of these temples.

Thus, at the time when these two temples were stated to have been built, each *might have been used* to observe one the rising, the other the setting, of an important star. We have long ago seen that so far the Egyptians, like the Babylonians at a later date, only had an idea of observing a heavenly body and the position of other bodies in relation to it, so long as it was rising or setting, so that it was absolutely essential that the body which they were to observe should rise and set. You know perfectly well that in London there are many stars which neither rise nor set. The latitude of London being 51°, the elevation of the pole therefore is 51°, and from the pole to the north point of the horizon being 51°: of course any star which lies at that distance from the pole cannot set, but sweeps round without touching the horizon at all. The latitude of Thebes being 25°, the distance from the pole to the horizon is much smaller, and so the number of stars which do not rise and set is much smaller. The stars which did not rise or set were stars which were moving very slowly and the stars which rose most to the north and most to the south were those bodies which were moving most slowly while they yet rose or set. Can this slow rate of motion have had anything to do with such stars being selected for observation, the brightest star to the north, most slowly moving, the brightest star to the south most slowly moving? It is possible that observations of these stars might have been made in such a way that at the beginning of the evening the particular position of γ Draconis might have been noted with regard to the pole star, if there were no other reason; and seeing that the Egyptians thoroughly knew the length of the night and of the day in the different portions of the year, they could at once the moment they got the starting point of the rising of this star practically use the circle of the stars round the north pole as the dial of a sort of celestial clock. May not this really have been the clock with which they have been credited? However long or short the day, the star which was at first above the pole star, after it had got round so that it was on a level with it, would have gone through a quarter of its revolution.

So much then for the possible use of the temples built by Rameses III. in the year 1200 B.C. It has already been pointed out that although we have in one an amplitude of 63° N. of E. we have other temples with amplitudes of 68° N. of E. and 71° N. of E. Everybody agrees that the temple, with amplitude 63° N. of E., was built 1200 years B.C. I have shown that that temple could have observed the most northerly star which did not set. May it not have been that the 68° temple and the 71° temple were temples built to observe the same star *before* this one was built, because we know they could not have observed the star *after* this one was built, since γ Draconis was decreasing its declination, therefore in previous times its declination would have been *higher*, and the amplitude therefore of a temple to observe it would have been greater.

Looking back to the German tables and other calculations, we find that with an amplitude of 68° we get a declination of 56°, and the same tables tell us that that declination was the declination of the same star γ Draconis 2000 years B.C. It does look as if in all probability we are dealing with a series of temples not twisted but built in different places.

Can we consider that the temple with an amplitude of 71° might have been used to observe that same star long before the temples were built with amplitudes of 68° and 63°? The amplitude of 71° gives us a declination of 58°, we then find the year in which that same star γ Draconis had that declination to have been about 3000 years B.C. So that it is not impossible that temple was built first of all to observe γ Draconis 3000 years B.C., that after a time the star changed its declination so much that another temple became necessary, and 1000 years afterwards the change again became large, and still another temple was built to observe it. The three temples may form one series.

The discussion is a little difficult because the orientation is very far towards the south and north, and therefore a hill a few miles off would make a difference of 2° or 3° in the orientation of the temple, and as yet we have no observations that throw light on this point.

We have then at Thebes alone three converging lines of evidence which all go to strengthen the view that these temples were really—whatever else they might have been—usable as solar and stellar observatories. The difference being of course that in the case of the solar temple

Digitized by Google

no large change of amplitude was necessary, but that in the case of every stellar temple after a lapse of a certain number of years depending upon the position of the star, the temple must be twisted round if it were wished to continue to make observations of the same star.

That raises an interesting question by the way. Long after the temple had been used for observation of a particular star, long after that temple line was blocked by extended building, if the horizon of these temples was left open it looks very much as if when another bright star came along it was laid hold of for a new set of observations. However that may be, it is rendered extremely probable, by the considerations I have brought before you, that the Egyptians 3000 years B.C. had been rendered practically conversant with the result of the precession of the equinoxes by the fact that they had to rebuild and alter their temples from time to time because the stars changed their declination. If that be confirmed by subsequent investigations, it will show that these Egyptians possessed a very much more profound knowledge of astronomy than they have received credit for, because it is stated that the precession of the equinoxes was discovered by Hipparchus. It looks as if the precession of the equinoxes was probably published by Hipparchus as the result of an examination of the untold wealth of Egyptian astronomical observations which has been unfortunately lost to the world.

This question of orientation is after all one which survives among ourselves. All our churches are more or less oriented, which is a remnant of old sun worship, and the church is not always oriented exactly to the east, but so that the light of the sunrising upon the Saint's day to whom the church is dedicated may be thrown along the chancel.

It has long been known that Stonehenge is oriented to the rising of the sun at the summer solstice. Its amplitude instead of being 26° is 40°; with a latitude of 51°, the 26° azimuth of Thebes is represented by an azimuth of 40° at Stonehenge.

The first of January is very near the winter solstice, but is not quite the winter solstice. If you look up the old records of the races that lived 2000 or 3000 years B.C., you will find that the different races began their year at different times, and even that the same race at different times began their year differently; the choice lay among the equinoxes and the solstices, and seeing that one of the very oldest temples at Thebes is oriented to sunset at the summer solstice we should not be at all surprised if investigation shows that when that temple was built more than 3000 years B.C., the Egyptian year really began in what we should call our summer. We have ample evidence of this. And I think there is little doubt that when Stonehenge was built it certainly was built by people who began their year with the summer solstice, which you will remember is the time of the year in which in many countries it is the habit still to light fires upon hills and so on.

The next point is, what was probably the use made of these temples besides determining the length of the year and regulating so far as they could the seasonal changes, the times of the solstices, the times of the equinoxes, and the various celestial phenomena?

We understand that in the very beginning of observations in all countries, the moment man began to observe anything, we saw that he began to observe the stars, and the moment men began to talk about anything they had seen they must have started by in some way or other defining the particular stars they meant.

They would obviously talk first of the brightest stars, and separate them from the dimmest ones; they would then discuss the stars which never set, and separate them from those which did rise and set; then they would take the most striking configurations, whether large or small; they would choose out the constellation of Orion or the Great Bear, and for small groups the Pleiades. These would attract attention, and be named before anything else. Then later on it would be imperative in order to connect their solar with their stellar observations that they should name the stars which lay along the sun's path in the heavens. They would confine their attention to a belt round the equator rather than consider the configuration of stars half-way between the equator and north pole. In all countries—India, China, Babylonia, Chaldæa, Egypt—they had a sort of girdle round the heavens, called by different names in different countries, and the use of this girdle of stars, which sometimes consisted of twenty-eight stations, sometimes of twenty-seven, and sometimes of only ten, was to enable them to define the place of the moon or of any of the planets in relation to any of these stars. That condition of things, that stage of thought, is brought well before us in the Jewish Scriptures.

In the Book of Job we read, "Canst thou bind the sweet influences of Pleiades, or loose the bands of Orion? Canst thou bring forth Mazzaroth in his season? or canst thou guide Arcturus with his sons?"

Here we have the difficulty which has met everybody in going back into these old records, because there was no absolute necessity for a common language at the time; it was open to everyone to call the stars any name they chose in any country, therefore it is difficult for scholars to find out what particular stars or constellations were meant by any particular words. In the revised version, Arcturus has given place to the Bear with its train, and even our most distinguished scholars do not know what Mazzaroth means. I wrote to Prof. Robertson Smith the other day to ask him to give us the benefit of his great knowledge, and he says that Mazzaroth is probably that band of stars round the ecliptic or round the equator to which I have referred, but he will only commit himself to the statement that it is a probable enough conjecture; other people believe that it was a reference to the Milky Way.

I mention this to show you how very difficult this inquiry really is. The "seven stars" undoubtedly mean the Pleiades and not the Great Bear. Among the brighter stars, Arcturus, the Pleiades, &c., are referred to by Homer and still earlier writers. So far as Egyptian and Chinese astronomy goes, practically the first reference to a constellation appears in Egypt with reference to the equinox which happened 3285 years B.C., and in China with reference to the Pleiades in the equinox of 2357 B.C.

In observing stars nowadays, we use a transit circle which is carried round by the earth so as to pick up the stars in different circles round the axis of the earth prolonged, and by altering the inclination of the telescope of this instrument we can first get a circle of one declination and then a circle of another.

The Egyptians did not usually employ meridian observations. Did the Egyptians make star maps? They certainly did. In the temple of Denderah, which is a comparatively modern temple, there is a very precious series of records which is certainly not at all modern. It represents a good many of the Egyptian constellations. The central part was in all probability the zenith point of Denderah itself, and at a certain distance from the centre point we have the zodiac represented excentrically. The constellations round the edge are those nearest the horizon; the central ones are those nearest the north pole; instead of having the Great Bear, we have the constellation of the Thigh, representing the well-known seven stars; in addition we have the constellation Hippopotamus, which has now entirely disappeared. There is also a Babylonian zodiac, which will show you that, although Babylonia and Egypt were adjacent countries, yet that they had a perfectly different set of constellations. Our present constellations came not from Egyptian times, but from much later—from Greek times. It is almost impossible to hope to recover the names of the

Digitized by Google

constellations used by people earlier than the Greeks, but still much is to be hoped from the study of the Babylonian records. In these we have a snail being drawn along by the tail of a snake or dragon. It is quite possible that we may have there the origin of our constellation Draco, which is the northern constellation, and it is quite possible that this snail may indicate that the stars in it moved with very great slowness. But it is impossible at present to co-ordinate these different fancies together.

A very important paper has recently been published by Mr. Le Page Renouf suggesting that before the year 1500 B.C. the Egyptians really had an idea of meridional observations. These observations are recorded in several manuscripts found in tombs; they seem to have been given as a sort of charm to the people who were buried in order to enable them to get through the difficulties of the way in the nether world.

The hieroglyphs state that a particular star of a particular Egyptian constellation is seen at a particular hour of the night; we have twelve lines representing the twelve hours of the night, and it is stated that we have in these vertical lines the equivalent of the lines in our transit instruments, and that the reference "in the middle," "over the right eye," "over the right shoulder," or "over the left ear," as the case may be, is simply a reference to the position of the star.

If this should be confirmed, one of the remarkable things about the inquiry will be that the Egyptians did not hesitate to make a constellation cover very nearly 90°. In those days evidently they wished to have as few constellations including as many stars as possible, in order perhaps that things might be more easily remembered.

When the zodiac of Denderah was mentioned, I pointed out the constellation of the Hippopotamus very near the north pole. This constellation is referred to in the records in question.

Such then are some of the ideas which are suggested by the recent work of the Egyptologists. You see, I trust, that it is important that this work should be continued as closely associated as possible with astronomical ideas, because, merely taking a very small part of the area of which they have begun the consideration, we have come to the conclusion that, dealing with the temples alone, there seems a very high probability that 3000, and possibly 4000 B.C. the Egyptians had among them men with some knowledge of astronomy, and that 6000 years ago the course of the sun through the year was practically very well known, and methods had been invented by means of which it might in time be better known, and that not very long after that they not only considered questions relating to the sun, but began to take up other questions relating to the positions and the movements of the stars. It is quite probable that 1500 years B.C. at least they had an idea of meridional observations. If this be so, and if more and more can be proved, I think you will agree that, as I said before, astronomy will have a slight opportunity of repaying some of the great debt which she owes to the other sciences.

J. NORMAN LOCKYER.

THE LATER LARVAL DEVELOPMENT OF AMPHIOXUS.

THE memoir by Mr. Arthur Willey, B.Sc., of University College, London, on this subject, in the *Quart. Journ. Microsc. Science*, March 1891, deserves more than a passing notice. It is one of the most important contributions which have been made to a knowledge of this very interesting animal. In the summer of 1889, Mr. Willey was sent by Prof. Ray Lankester with the aid of a Government grant to collect the larvæ and embryos of Amphioxus at Faro, near Messina. He returned with a large series, and in the winter 1889-90 worked out in the laboratory of University College, chiefly by means of sections, the history of the formation of the atrial cavity in this animal. In a paper published jointly by Prof. Lankester and Mr. Willey (*Quart. Journ. Micr. Sci.*, August 1890), it was shown that the atrial cavity does not form, as supposed by Kowalewsky and by Rolph, as the result of a down-growth of lateral epipleura; but that it forms as a longitudinal groove which sinks inwards along the ventral surface, becoming floored in by a small horizontal growth on each side corresponding merely to that portion of the adult animal's ventral surface which lies between the two metapleura. The groove, now become a narrow tube, expands right and left, until it acquires the proportions of the adult atrial chamber.

The preserved material brought home by Mr. Willey in 1889 did not enable the observers to determine the mode of origin of the second row of gill-slits. Stages were noted in which there were as many as fourteen gill-slits of the first series (which are placed anteriorly on the animal's right side), and stages were observed, of no greater size, in which two rows of gill-slits were present—one series on the right side and one on the left side of the pharynx; whilst the mouth, which in the specimens with a single series was completely lateral (on the left side), had now taken up a median position.

Mr. Willey again visited Faro in the summer of 1890, for the purpose of determining, by the study of living transparent larvæ, exactly the mode of origin of the second row of slits, and the steps in the "symmetrization" of the larva. The brief account and few unconvincing figures given by Kowalewsky, in 1866, in relation to this matter had not commanded general confidence, although it was felt that so accurate and accomplished an observer could not have been completely mistaken. Balfour had said, in reference to Kowalewsky's observations on this matter, that he was "tempted to suppose that his observations were made on pathological specimens."

Mr. Willey completely and most successfully accomplished the object which he set before himself in his second visit to Faro, and the results obtained are given in the paper under notice, illustrated by three folding-plates. He confirmed the main feature of Kowalewsky's observations, viz. that the first row of gill-slits, after having (so far as the first eight are concerned) taken up a position on the *right* side of the pharynx, rotate downwards across the median ventral line, and rise up into position on the *left* side, whilst, simultaneously, a new series appears on the right side, not one by one, but as many as six being formed at approximately the same moment. Mr. Willey corrects Kowalewsky's brief account in one or two numerical details, and adds some very important facts, which are quite new. He shows: (*a*) that the anteriormost slit of the primary series closes up and disappears during the process of rotation; (*b*) that some of the hinder slits of this series, which are not far advanced when the rotation begins (there being usually fourteen, of which the last six are very small, and lie in the median ventral line), also close up; so that, when the rotation is complete, and the second series of gill-slits has advanced in development to the number of eight, a "critical phase" is reached in which there are only *eight* gill-slits on each side of the pharynx, all fairly well developed. From this time forward new gill-slits are formed on each side behind the last formed, and continue to increase in number so long as growth continues, which appears to be as long as the Amphioxus lives.

But the most important discovery made by Mr. Willey is as to the origin of the endostyle, a structure which has great importance from the fact that it can be clearly identified, on account of its minute histological structure, with the endostyle of the Ascidians.

In the anterior region of the buccal cavity, previous observers have described in very young Amphioxus larvæ (with only one gill-slit) an elongated gland; "the club-

shaped gland." It opens to the exterior on the left side, just in front of the big laterally-placed mouth, whence it can be traced, bending down across the median line and passing up at *right angles* to the long axis of the body along the deep surface of the right wall of the buccal cavity. It opens at its apex, as Mr. Willey has shown, into the buccal cavity. Its earliest appearance (as described by Hatschek) resembles that of a gill-slit, though it precedes both the mouth and the first gill-slit in date. Mr. Willey suggests that it is a modified gill-slit. By the side of this club-shaped gland and in front of it, immediately associated with it, is a band-like tract of modified but the <-shaped epithelial tract does not; it grows rapidly at its angle along the line or interspace between the two series of slits, forming a double tract of modified epithelium consisting of parallel extensions of the two limbs of the <. It is now the epithelium of the hypopharyngeal ridge or endostyle.

Mr. Willey regards the club-shaped gland so intimately associated with the first stages of the endostyle as a modified gill-slit belonging to the secondary (the permanent right-side series). Its early development in *front* of the mouth indicates this; since, when the mouth acquires a median position (passing from the left towards

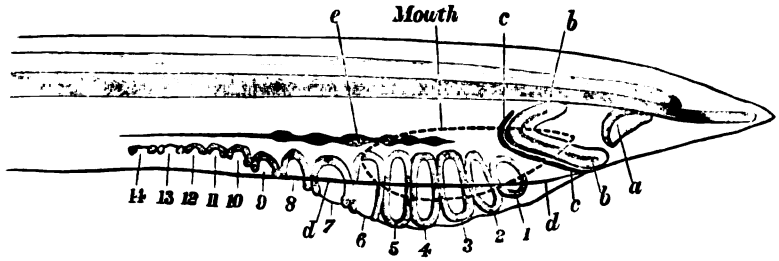

FIG. 1.

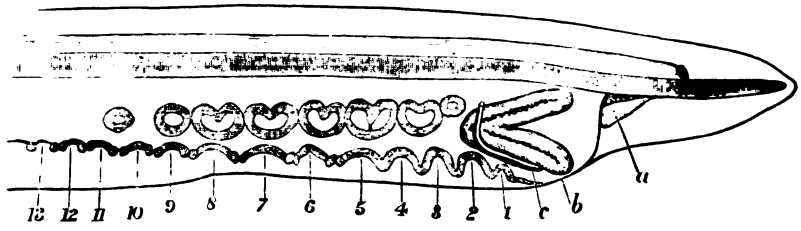

[FIG. 2.

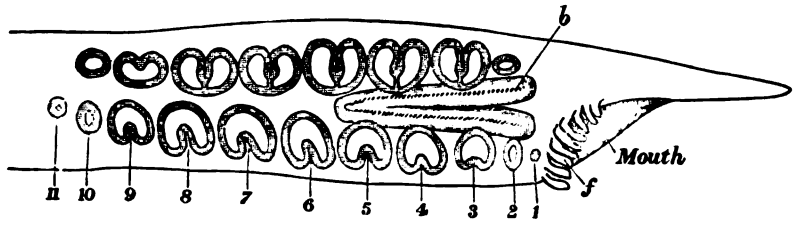

FIG. 3.

FIGS. 1, 2, 3.—Diagrams showing three stages in the development of the gill-slits and endostyle of Amphioxus. Figs. 1 and 2 are seen from the right side; Fig. 3 from the ventral aspect. In Fig. 1 the position and shape of the mouth, which lies on the left side of the animal, are indicated by a dotted oval. The primary series of gill-slits are numbered in all the figures. The secondary series are not numbered. Fig. 2 shows the rotation downwards of the primary series of gill-slits and their nearly complete disappearance from view on the right side; at the same time the secondary series have developed to the number of eight, and the endostyle has become <-shaped, and is pushing its angle between the two rows of gill-slits. Fig. 3 shows the atrophy of the most anterior primary gill-slit, whilst some of the hindermost have disappeared and numbers 10 and 11 are in course of closure and disappearance. *a*, præoral ciliated pit, opening on the animal's left side, but seen through the transparent integument; *b*, the endostyle (<-shaped tract of modified epithelium); *c*, the club-shaped gland; *d*, the edge of the right meta-pleur (the atrial cavity is not yet formed in the anterior pharyngeal region); *e*, the six thickenings which develop the six anterior gill-slits of the secondary (permanent right-side) series; *f*, the præoral tentacles.

intra-buccal epithelium. When there are about eight gill-slits of the primary series present, it is noticeable that the apex of the club-shaped gland is bent over, so that the gland tends to become <-shaped, with the angle directed backwards; the adjoining epithelial tract faithfully follows the bend. At first the upper limb of the < is a good deal smaller than the lower, but as the primary series of gill-slits move from the right side of the pharynx to the left, the two limbs of the < become nearly equal in length, and the angle takes up a position between the primary and the new secondary series of slits. The club-shaped gland-tube now atrophies entirely, the right by a relative growth, the reverse of that which brings the primary gill slits from the right to the left!), structures just in front of it would be thrown round to the right side, the side of the secondary series of slits. He suggests that it is the early-developed anterior member of the secondary series of gill-slits; and points out that just as this modified gill-slit atrophies, so does its pair in the primary series, viz. the first.

Mr. Willey points out the possible importance of these facts in reference to the views of Dohrn and of Van Beneden, and makes an interesting comparison between the Ascidian tadpole and the Amphioxus larva, with a

Digitized by Google

view to suggesting some explanation of the extraordinary asymmetry of the latter. Mr. Willey thinks that a cause of the one-sided position of the mouth and of the primary series of gill-slits in the Amphioxus larva may be found in the excessive anterior prolongation of the notochord at an early period of development, necessitating a pushing to either one side or the other of the mouth. There appears to be nothing in the mode of life of the larva—a free-swimming ciliated creature—which can be correlated with its asymmetry. The gradual process of "symmetrization," by which the Amphioxus establishes more or less completely a bilateral symmetry on its way to the adult form, is exactly the converse of that process by which the symmetrical larva of the Pleuronectid fishes becomes one-sided; but in the latter case the asymmetry is clearly correlated with a peculiar life on the sea bottom, whilst in the former case we can discover no such relation to environment. E. R. L.

THE CARDIFF MEETING OF THE BRITISH ASSOCIATION.

TO arrange for the reception of the members of the British Association who will visit Cardiff in August next, an influential Local Committee has been formed, with the Most Honourable the Marquis of Bute, K.T., Mayor of Cardiff, as Chairman, and a substantial sum has been subscribed for the purpose of defraying the cost of the meeting.

Several sub-committees have been formed, all of which report to the Executive Committee, to which also the Council of the British Association has assigned the duty of electing new members and associates. Up to the present time 7 life members have been added, and over 200 annual members and associates, and as the time for the meeting approaches the number of new members and associates will be largely increased.

It may be convenient to describe what has been done by the sub-committees, so as to give a systematic account of the preparations already made and in progress to provide for the comfort and entertainment of our expected visitors.

(1) *Hospitality and Lodgings.*—Many of the principal residents in Cardiff and the neighbourhood have signified to the Committee their desire to entertain members of the Association, and as the date of the meeting draws nearer numerous additional offers will be made by those of the townsmen who are unwilling or unable to fix their engagements so long beforehand. It is understood that those ladies and gentlemen who have offered to invite guests will send out invitations as soon as it is known to the Committee who are coming.

The hotel and lodging accommodation is not so great as in some other towns, but the Committee feel sure that with the private hospitality which will be offered there will be enough for the needs of our visitors. The list of hotels and lodgings will be ready for distribution about the middle of July, it having been delayed to make the list as complete as possible. The list will be accompanied by a map of Cardiff taken from the most recently executed ones.

(2) *Reception and Section Rooms.*—The reception room will be at the Town Hall, practically the whole of which has been placed at the disposal of the Local Committee for the use of the Association. The vestibule will be devoted to the sale of tickets, the distribution of programmes, and other information, whilst the Assembly Rooms will be fitted up as a drawing-room with writing-tables, post-office facilities, and a book-stall. The Council, Committee of Recommendations, and General Committee will meet in various rooms, and others will be set apart for the officers of the Association.

As the Town Hall is about half a mile from the Section room furthest away, a portion of the Drill Hall, the use of which has been kindly granted by Lord Bute, Colonel Gaskell, and Colonel Page, will be fitted up as a drawing-room, and the remainder will be used as a luncheon-room. As the Drill Hall is situated within very easy distance of almost all the Section rooms, the members of the Association will doubtless appreciate the advantage of having a drawing-room and dining-room so close at hand.

The majority of the Section rooms are very close together, and the greatest distance is not more than half a mile; tramcars and busses, however, run frequently between the extreme points, so that even that distance should offer no difficulty in the way of members wishing to attend different Sections.

(3) *Entertainments.*—The usual *conversazioni* will be given on Thursday, August 20, and on Tuesday, the 25th, and it is hoped that scientific men will aid the Committee in contributing towards the entertainment of our guests by the exhibition of novel experiments or specimens. The Park Hall, in which the *conversazioni* will be held, is well suited to this purpose, and it is the desire of the Committee to introduce as many scientific novelties as possible.

A garden party, to which all members of the Association will be invited, will be given by Lord and Lady Bute, probably on the Friday afternoon, though the date may be subject to alteration. Other social entertainments are projected by Lord Windsor and others, and Cardiff will probably in this respect not fall behind what the members have been accustomed to at other places of meeting.

(4) *Excursions.*—A considerable variety of excursions has been provided for both the Saturday and the following Thursday. For the former, arrangements are being made by Sir W. T. Lewis for a party of members to visit the Cardiff Docks; by a committee appointed by the Board of Directors to visit the Barry Docks; by the Mayor of Newport and the Chamber of Commerce for a party to visit Newport and Caerleon. A special excursion is being arranged by the Colonel commanding the Severn Valley division of submarine miners for officers of the British Army to inspect the Severn Valley defences. The steamer will land the officers at the steep and flat holmes, and will continue with the civilians on board to Weston, from which they will visit Worlebury Hill and camp.

Other excursions will be of geological and archæological interest, and will include excursions to Penarth and Lavernock, where the finest section of Rhætic beds in England is exposed; to the interesting dolmens at St. Nicholas and St. Lythan's; to Llantwit-major, where a year or two ago the remains of a Roman villa were unearthed, and where a college is said to have existed in the fourth century; to Tintern Abbey and Raglan Castle, the Forest of Dean, Merthyr, Brecon, and to some of the numerous collieries and iron-works in the South Wales coal-field. A practical natural history excursion is being organized by the Cardiff Naturalists' Society to the Vale of Neath, which from the beauty of the spot should prove attractive. Several owners of works in the neighbourhood of Cardiff have expressed their willingness to throw them open to the members, and arrangements will be made for visits to some of them.

(5) *Publications.*—A guide-book to Cardiff is being prepared for distribution to all members and associates, and the descriptive articles have been intrusted to the gentlemen who were best fitted to write them. The article on the history and archæology of Glamorganshire has been written by the veteran G. T. Clark, of Dowlais, whilst that on the topography of Cardiff was undertaken by the late James A. Corbett, who, unfortunately, died before it was quite complete. Mr. T. Forster Brown, President of Section G, has undertaken the description of the mining, geological, and statistical features of the district; the industrial portion being in the hands of Mr.

Digitized by Google

Galloway. The geological, zoological, and botanical descriptions have been written by Mr. T. H. Thomas and Prof. W. N. Parker, with the help of many others. The account of the educational arrangements of Cardiff will be treated of by Mr. Whitmell, Inspector of Schools, and Principal J. V. Jones.

The excursions hand-book will contain a map, on a scale of four miles to the inch, of the whole of the district in which the excursions will be held, specially prepared for the Committee by Messrs. Bartholomew and Co., Edinburgh. As detailed accounts as possible of the various points to be seen in the excursions will be given by those having special knowledge: taken together with the guide-book, it is thought that a very complete description of everything connected with this portion of South Wales will be furnished to the visitors.

Other Committees have been formed for the evening lectures and the working men's lecture, but little more can be said about them than that they will provide to the fullest extent for the wants of the Association. The Local Committee are anxious that this shall be the case in every particular, so that the first visit to the metropolis of Wales will not suffer in comparison with previous meetings of the Association. R. W. ATKINSON.

MARINE BIOLOGICAL ASSOCIATION OF THE UNITED KINGDOM.

WE have received the annual report of the Council of this Association, presented at the general meeting on June 24—the President, Prof. Ray Lankester, F.R.S., in the chair. In the sea, as well as on land, the severe winter appears to have had a marked effect on the fauna, and there is also a complaint of mortality in the aquarium attached to the Laboratory during the colder months; a result perhaps somewhat unexpected, considering the comparatively high winter temperature of the sea. We are glad to learn that a self-sown fauna is springing up in the tanks, the condition of which is said to be steadily improving, as is the case with all aquaria after one or two years of use.

Under the head of the library (which ought to be represented in the balance-sheet by a larger sum than is at present debited to it) the Association is to be congratulated on having received the gift of the late Mr. Spence Bate's library, constituting an exceedingly valuable collection of the literature of Crustacea.

Some of the changes made in the permanent staff have been chronicled already: Mr. Calderwood has replaced Mr. Bourne as Director, and has appointed Mr. H. N. Dickson to succeed Mr. Garstang, who took up a Fellowship at the Owens College in December last. Two temporary members have been added to the staff: Mr. F. Hughes, to carry out from the chemical point of view an inquiry into the possibility of manufacturing an artificial bait; Mr. E. W. L. Holt, known already as the author of some papers on Teleostean development, to conduct investigations into the immature fish question as regards the Dogger Bank and the region eastwards of it—the lines of this latter inquiry are sketched in an appendix to the report. Among the fishery investigations of the past year are quoted experiments on the rate of growth and the age of sexual maturity in food-fish, oyster and lobster culture, and the anchovy fishery which the Association desires to initiate. We are glad to see that systematic physical observations are to be taken at the Laboratory in future.

Eleven gentlemen have visited the Laboratory during the year for the purposes of research, some of them on more than one occasion. This number, however, is by no means as large as it should be.

The balance-sheet shows a satisfactory, if small, increase in receipts, the items pointing to an increased use of the Laboratory, both for research and for the purchase of material for teaching purposes. A sum of £500 (in addition to the annual grant of £500) has been placed on the Civil Service estimates for the current year, which will, if passed, place the Association in a position to carry on its work with less difficulty than has hitherto been the case.

UNIVERSITY EXTENSION STUDENTS AT CAMBRIDGE.

THE work done by University Extension students at Cambridge last year was so satisfactory that the Syndicate for local lectures are encouraged to repeat the experiment this year. They will be prepared to receive a larger number of students, say from 60 to 80, most of whom will be lodged either at Selwyn College or at Newnham College. The period of study will last from July 28 to August 22, or nearly a month in all. The Syndicate have just issued a detailed programme of the various courses of study; and we are glad to see that due attention has been paid to the claims of science as well as to those of literature and art. At the chemical laboratory, on alternate days, there will be a course of demonstrations illustrating the methods of chemical manipulation in a short series of typical experiments. The pupils will be first shown each experiment, and will then be expected to repeat it for themselves. At the Cavendish Laboratory, on alternate days, a course of short experimental lectures, chiefly on electricity and magnetism, will be delivered; and most of the experiments shown in the lectures will afterwards be performed by the students for themselves. Geology will be studied, on alternate days, at the Woodwardian Museum, where there will be a course of demonstrations on the leading fossil types of the animal kingdom, from the specimens in the Museum. A course of demonstrations, followed by practical work, will be given, on alternate days, in the physiological laboratory; and Mr. Graham, chief assistant at the Observatory, will receive students and explain the uses of astronomical instruments. Arrangements will also be made for taking small parties of students to the Observatory at night. Single lectures will be delivered by various eminent Cambridge men, and in this part of the work science will be represented by Prof. G. H. Darwin, who will lecture on the history of the moon or some allied subject. We may note that the students in science will be allowed to read in the Philosophical Library.

NORMAN R. POGSON, C.I.E.

WE regret to have to announce the death of Mr. Norman Pogson, for thirty years the Director of the Observatory at Madras. Mr. Pogson has been so long absent from England that, in a sense, he may be said to have outlived his reputation; but those who can recall the condition of astronomy in this country some thirty years since will remember him as a rising astronomer of considerable promise, and as one of the most indefatigable observers at that time. If his subsequent career has not entirely fulfilled his early promise, perhaps the condition of the Madras Observatory is to some extent the cause. We believe that its astronomical equipment is very old and inadequate, and possibly Mr. Pogson has accomplished all that could be done with his instruments and his staff.

Mr. Pogson's astronomical career commenced at Mr. Bishop's Observatory in Regent's Park, at that time under the direction of Mr. J. R. Hind, and he there took part in the observations for forming the ecliptic charts published from that Observatory. In 1851 he left London

Digitized by Google

to assume an assistantship in the Radcliffe Observatory, Oxford, under the late Mr. Johnson; and there his zeal was rewarded by the discovery of several minor planets, in days when the number of the known asteroids was comparatively small, and their discovery conferred some little distinction upon their fortunate discoverer. Of greater importance to astronomy was his subsequent devotion to variable stars and photometry, the latter carried out, we believe, with the apparently inappropriate instrumental means of the heliometer of the Radcliffe Observatory, Oxford. But the result of his investigation of the amount of light that separates two consecutive magnitudes has never been displaced, and the fortunate employment of the number, whose logarithm is 0·4, to express this ratio will probably long connect Mr. Pogson's name with the history of accurate photometry.

After a somewhat short stay at the Hartwell Observatory, Mr. Pogson left England in 1861 to take charge of the Madras Observatory. His direction of that institution will always be remembered in connection with the extraordinary discovery of a telescopic comet, effected in consequence of the telegraphic communication he received from Prof. Klinkerfues, who expected that Biela's comet might be seen in the constellation Centaur, after the brilliant meteoric shower to which that comet had given rise in November 1872. Mr. Pogson looked in the direction indicated, and by a remarkable coincidence found a comet, which he observed on two, and only two, occasions. The orbit remains, therefore, indeterminate, but there is good reason to believe that the object seen was in no way connected with either of the two condensations which together make up the lost comet of Biela. And thus another and not uninteresting chapter was added to the history of this comet. Several volumes of observations have been published under Mr. Pogson's direction; the last bears the date of 1870, so that probably, and as the Director has often lamented, the reductions are considerably in arrear.

It will be interesting to watch the future of this Observatory. It is to be hoped that some steps will be taken to place it more in accordance with the requirements of the present time. We believe that its abandonment has even been canvassed, but it cannot be sufficiently regretted if an Observatory, possessing as that does many historical associations, and occupying a very favourable position on the earth's surface, be allowed to disappear.

W. E. P.

NOTES.

THE death of Wilhelm Weber, the illustrious physicist, is announced. He died at Göttingen on June 23. On a future occasion we shall give some account of his services to science.

THE second lecture in connection with the Faraday Centenary was delivered by Prof. Dewar, F.R.S., at the Royal Institution on Friday evening last.

ON Tuesday, Lord Cranbrook, in the House of Lords, moved the second reading of a Bill the object of which is to allow the managers of science and art schools to transfer them to local authorities when they desire to do so. Lord Cranbrook explained that at present there were considerable difficulties in the way, and that the process was a very long and tedious one. The Bill proposed to make these schools transferable in the same way as ordinary schools could be transferred to School Boards. The Bill was read a second time.

DRS. J. BORNMÜLLER AND P. SINTENIS propose to occupy the present summer with an investigation of the flora of the islands Samothrace and Thasos, from which very few collections are to be found in European herbaria; also of Mount Athos and of the Bithynian Olympus. They then intend to take up their winter quarters in Mossul, and to spend the following spring and early summer in the comparatively unknown mountainous region of Djebel Hamzin near Bagdad, and the mountains to the north and east of Mossul.

THE distinguished Italian botanist, Prof. O. Penzig, is about to start on a botanical expedition to Massowah and Bogos.

MR. J. T. NICOLSON, at present Prof. Ewing's demonstrator in the University of Cambridge, has been appointed to the Chair of Mechanical Engineering in the McGill University, Montreal.

A STALL for the sale of "zoological photographs" has just been opened in the Zoological Society's Gardens. It is placed in the centre of the Gardens, near the band-stand, and has an attractive exterior. The photographs sold are mostly representations of animals in the Society's Gardens, but also include some taken in the Jardin d'Acclimatation of Paris, and in other similar establishments.

THE marine laboratory of the Johns Hopkins University will be open this summer at Port Antonio on the north-east coast of Jamaica. According to *Science* of June 19, Prof. Brooks and some members of his party had already started for the station.

THERE has been lately formed in Berlin (we learn from *Naturw. Rdsch.*) a "Union of friends of Astronomy and Cosmical Physics," with the view of organizing practical co-operation in these subjects of research in Germany, Austria, Hungary, Switzerland, and neighbouring countries, and also in the colonies, and where membership may be desired. The object is to be sought by means of free communications of the members or groups of members to head-quarters, whence advice and results of observations, &c., will be issued. Sections are formed for observations (1) of the sun; (2) of the moon; (3) of the intensity and colour of starlight and of the Milky Way; (4) of the zodiacal light and meteors; (5) of polar light, terrestrial magnetism, earth currents, and atmospheric electricity; and (6) of clouds, halos, and thunderstorms. Prof. Lehman-Filhés has been elected President of the Union, and the presidents of the sections are Förster, M. W. Meyer, Plassmann, Jesse, Weinstein, and Reimann.

ACCORDING to a telegram sent through Reuter's Agency from San Francisco on June 29, a series of sudden sharp earthquake shocks, accompanied by subterranean rumblings, passed through San José, California, that morning. The first shock was so violent that the electric-light tower, two hundred and forty feet high, swayed for at least ten feet. A panic prevailed in the town; and in two of the principal hotels, which were filled with tourists from the East, men and women rushed half-dressed from their rooms into the corridors in a great state of alarm. The city rocked like a ship in the trough of the sea, and when the second shock occurred, buildings rose and fell with a slow undulating motion, one partly erected brick building tumbling to the ground. Many chimneys fell, and a large number of windows were broken, while considerable damage was done to crockery and other fragile articles in the houses.

GERMANY had very heavy rains on November 22 to 24 last year, causing floods at a rather unusual time in the region of the Elbe, Weser, &c. It is shown by Prof. Hellmann, that Middle and West Germany were then on the front side of a deep depression, which passed very slowly from north to south, taking about 90 hours from the North Sea to Central Germany, less than half the usual speed from west to east. A region of high pressure with cold lay to the east, blocking the course in that direction, and this afterwards spread over the flooded country, covering it with ice.

THE Central Meteorological Observatory at Tokio, Japan, has begun the publication of hourly meteorological observations, commencing with January 1890. The observations are contained in monthly Bulletins, and include all the usual elements, together with vapour tension, humidity, earth temperature, bright sunshine, and hourly and daily means. Meteorological observations have been made for some years in various parts of Japan, including hourly observations at Tokio since January 1, 1886, but have hitherto only been published for certain hours. The observations are all made without self-recording instruments, excepting those of wind and sunshine. Some years ago the Director of the Service, I. Arai, visited this country, and other European countries, for the purpose of studying the various meteorological organizations, and we have no doubt that this important publication will be very valuable for meteorological researches referring to the North Pacific Ocean, where information is comparatively scanty.

M. MASPERO has an interesting article in the current number of *La Nature* on the dog in ancient Egypt. It is illustrated by representations of dogs reproduced from Egyptian monuments, and by a mummy of a dog recently opened and sketched by M. Beckmann. In ancient Egypt, as in modern Europe, the dog was regarded both as a friend and as a useful servant. He also received the honours of a god, and there are cemeteries of dogs (corresponding to the cemeteries of cats) where mummies have been found by the thousand. Attempts have been made to identify the various species of dogs represented in wall paintings, but those naturalists who have investigated the subject have not always arrived at the same conclusions. M. Maspero points out that mummies supply more trustworthy materials for study, and urges that men of science should lose no time in examining some of them, as cemeteries of animals are being very rapidly "exploited."

A COMMERCIAL company has for some time been working quarries in the neighbourhood of the well-known glacial grooves at Kelley Island, Ohio; and it was feared that these remarkable relics of the glacial epoch might be wholly destroyed. Fortunately the president of the company understands the interest of the phenomena, and has taken care to prevent the most striking of them from being injured. We learn from the Cleveland *Leader* that some of the grooves have now been rendered safe, the company at its recent annual meeting having decided that the rocks on which they are furrowed should be made over to the president, by whom they will be transferred to a scientific or historical society, "to be preserved in perpetuity for the benefit of science."

MR. C. DAVIES SHERBORN is, we are glad to find, making satisfactory progress with the stupendous task he has undertaken in the production of his "Index Generum et Specierum Animalium." Mr. Sherborn has found it absolutely necessary to accept the year 1758, the date of the tenth edition of Linnæus's "Systema," instead of the twelfth edition (1766), as the starting-point of binomial nomenclature in zoology, and this decision was greatly strengthened by the advice of Prof. Sven Loven, Dr. D. Sharp, and others who had carefully studied the question. This is the only alteration which has been made in the original scheme (see NATURE, vol. xlii. p. 54). During the year, five hundred volumes have been worked through, page by page, and a total of forty thousand species have been recorded, *in duplicate*, involving a use of 80,000 slips. Each species is recorded on a separate slip (5 inches × 2½), the whole of the *reference*, with the sole exception of the page, being printed with india-rubber type, thus insuring perfect accuracy of date and parts of volumes: as the pages are also checked during work, the chances of misquotation are reduced to a minimum. As the volumes mentioned include the whole of the publications of Linnæus, many of Fabricius, Thunberg, and other voluminous authors of that early period, it is, perhaps, permissible to think that more rapid progress may be made in future years. The dates of publication of the separate parts of a work have been carefully attended to, and much valuable information has been obtained. Some of this has appeared in the *Annals of Natural History* (Pallas's "Icones Insect.," "Nov. Spec. Quad.," and White's "Journal"), while much remains in manuscript until the final completion of detail admits of its publication. As is well known, the authorities of the Natural History Museum have rendered every facility to Mr. Sherborn for the prosecution of his work, and the storage of the manuscripts within the walls of that institution, reducing the risk of loss by fire to a minimum, is a concession highly valued by the author. One set of the slips is arranged in order of genera, and, on application, is available for reference to anyone compiling a monograph of a genus. The manuscript is frequently consulted by those working at the Natural History Museum, even in its present imperfect state, and will, from the very nature of the method of recording, prove of increasing value as it grows to larger proportions.

IN the report of the trustees of the South African Museum for 1890 it is stated that the curator, Mr. R. Trimen, has completed a thorough rearrangement of the fine collection of South African Diurnal Lepidoptera in accordance with the monograph of those insects recently published by him, incorporating many additional species, and replacing imperfect or worn examples by fresher and more characteristic specimens. He has also begun the rearrangement of the more numerous and less known Crepuscular and Nocturnal Lepidoptera. Mr. Trimen has completed for publication two papers—one on the very interesting series of butterflies collected in South-West Tropical Africa by Mr. A. W. Eriksson, and presented by that explorer to the Museum in 1888; and the other on some additions to the list of extra-tropical South African butterflies since the publication of the concluding volume of his work.

AN interesting account of the nest and eggs of the cat-bird (*Ailuræedus viridis*, Latham) is given by Mr. A. J. North in the latest number of the Records of the Australian Museum (vol. i., No. 6). The habitat of the cat-bird is the dense scrubs of the coastal ranges of New South Wales. Although the bird is common, authentic specimens of its nest and eggs seem to have been unknown until lately. For an opportunity of examining such specimens, Mr. North is indebted to Mr. W. J. Grimes, an enthusiastic oologist, who recently secured two nests of this species on the Tweed River. The nest is a beautiful structure, being bowl-shaped, and composed exteriorly of long twigs, entwined around the large broad leaves of *Ptarietia argyrodendron*, and other broad-leaved trees, some of the leaves measuring eleven inches in length by four inches in breadth. The leaves appear to have been picked when green, so beautifully do they fit the rounded form of the nest, one side of which is almost hidden by them. The interior of the nest is lined entirely with fine twigs. The eggs are two in number for a sitting, oval in form, being but slightly compressed at the smaller end, of a uniform creamy white very faintly tinged with green, the shell being comparatively smooth and slightly glossy. Although the cat-bird is usually included in the family of bower-building birds, Mr. North has never known or heard of its constructing a bower.

A CATALOGUE of the Australian birds in the Australian Museum, at Sydney, by Dr. E. P. Ramsay, is being published. Part III., which has just been issued, deals with Psittaci.

AS a substance peculiarly fitted, by reason of its high dispersive power, and transparency for ultra-violet rays, for study of the ultra-violet part of the spectrum, Herr Wolter has recently recommended, in a Hamburg serial, α-monobromnaphtalin.

Digitized by Google

With a prism of the liquid, he could trace the spectrum beyond N on a fluorescein-solution. Besides the above-named properties, the substance has for boiling-point 277° C.; it has no offensive smell like carbon sulphide, and its index of refraction varies much less with temperature than in the case of that liquid.

THE material resources of the southern part of Maryland are still so imperfectly known that a scientific expedition for the investigation of the district was recently organized. The expedition was formed under the joint auspices of the Johns Hopkins University, the Maryland Agricultural College, and the U.S. Geological Survey. An interesting report of the work done has been published in one of the Johns Hopkins University Circulars.

DR. ALFRED TUCKERMAN has compiled an excellent "Bibliography of the Chemical Influence of Light," which has been published as one of the Smithsonian miscellaneous collections. As the compiler had in view only the scientific aspects of the subject, he has omitted nearly all the practical applications, including that of photography. An index to the literature of photography is being prepared under the auspices of the committee for indexing chemical literature, of the American Association for the Advancement of Science.

THE College of Science, Imperial University, Japan, has issued the first part of the fourth volume of its Journal. It opens with a paper on the fœtal membranes of Chelonia, by K. Mitsukuri. After this come the following articles:—On the development of Araneina, by Kamakichi Kishinouye; observations on fresh-water Polyzoa, by A. Oka; on *Diplozoon nipponicum*, n. sp., by Seitaro Goto; a new species of Hymenomycetous Fungus injurious to the mulberry tree, by Nobujiro Tanaka; notes on the irritability of the stigma, by M. Miyoshi; notes on the development of the suprarenal bodies in the mouse, by Masamaro Inaba. Each of the papers is illustrated.

MR. C. C. VEVERS, Leeds, has sent us a copy of the fourth edition, illustrated, of his "Practical Amateur Photography." The volume is described in the preface as "a simple text-book for the beginner, and a handy work of reference for the advanced photographer." Mr. Vevers has also published an illustrated catalogue of photographic apparatus.

THE Manchester Microscopical Society has issued its Transactions and Annual Report, 1890. The volume includes two Presidential addresses by Prof. Milnes Marshall, papers and communications read by the members, and a list of members.

WE have received from Mr. William F. Clay, Edinburgh, a catalogue of scientific books which he offers for sale. The works relate to chemistry and allied sciences.

AS briefly announced in our report of the last meeting of the Paris Academy of Sciences a new compound of iron and carbon monoxide has been obtained by M. Berthelot, analogous to the nickel compound described last year by Messrs. Mond, Lang, and Quincke. In order to obtain it, the iron requires to be in a very finely divided state, and free from admixed oxide. It is most suitably obtained by reducing dried precipitated ferric oxide or oxide obtained by ignition of ferrous oxalate in a current of pure hydrogen. When carbon monoxide is led over metallic iron thus prepared, and the tube containing it gently warmed to about 45° C., the reaction commences, and if the issuing gas, after being washed through water, is ignited at a jet, the flame is observed to be quite different from that of pure carbon monoxide, being brilliantly luminous, almost white, and emitting rays which furnish a definite spectrum. Moreover, if a cold porcelain tile or evaporating basin is depressed upon the flame a deposit of metallic iron more or less admixed with oxide is obtained, indicating the existence in the issuing gas of the vapour of a ferruginous compound. A drop of dilute hydrochloric acid at once dissolves the stain, and the solution affords the ordinary reactions of iron, yielding Prussian blue with potassium ferrocyanide for instance. When the gases are passed through a strictured tube, such as is employed in Marsh's arsenic apparatus, a portion of which is heated to redness, an annular deposit of metallic iron is obtained, containing a slight amount of admixed carbon. M. Berthelot has not yet succeeded in obtaining sufficient of the new compound to condense it to the liquid form, but further experiments with that end in view are in progress. The formation of this volatile compound of iron and carbon monoxide will undoubtedly prove of great interest from a metallurgical point of view, as it may assist in elucidating several of the as yet little understood furnace reactions. M. Berthelot further expresses the opinion that it may help to explain the formation of bubble flaws in manufactured iron, which have so frequently led to such unfortunate results. In addition to the preparation of iron-carbonyl, M. Berthelot describes several new reactions of nickel carbonyl. It will be remembered that this substance is a liquid boiling at 46°, so volatile that, according to M. Berthelot, its vapour tension at 16° is a quarter of an atmosphere. A drop placed upon a glass plate rapidly volatilizes, the portion last to disappear being for a few moments cooled down by the evaporation of the first portion to such an extent as to form beautiful little crystals. When suddenly heated to 70° it detonates, the detonating reaction being expressed by the equation $Ni(CO)_4 = 2CO_2 + 2C + Ni$. When mixed with oxygen, simple agitation of the tube containing it over mercury brings about detonation. When oxygen is permitted to slowly gain access to the liquid oxide, a solid substance is formed, which is green if the oxygen is moist and brownish-yellow if dry. In contact with oil of vitriol the liquid compound appears to be unaffected for a few moments, but suddenly explodes with production of flame. Nitric oxide reacts in a most beautiful manner, either when passed into the liquid or its vapour, bright blue fumes being produced of a complex compound, which eventually subside, forming a blue solid. These blue vapours completely fill the whole vessel, and their formation affords one of the prettiest experiments yet described.

CONTEMPORANEOUSLY with the above work of M. Berthelot, Mr. Mond and his co-workers have also been conducting experiments with the view to the preparation of iron carbonyl, which have been so successful that a brief account of them was laid before the Chemical Society at their last meeting. Further particulars of these experiments will be given as soon as published.

THE additions to the Zoological Society's Gardens during the past week include a Rhesus Monkey (*Macacus rhesus* ♀) from India, presented by Mr. Albert Job; an American Red Fox (*Canis fulvus*) from North America, presented by Mr. W. Reading; a Two-spotted Paradoxure (*Nandinia binotata*) from West Africa, presented by Mr. E. G. Parkinson; a Sinaitic Ibex (*Capra sinaitic*) from Palestine, presented by Sir James Anderson; two Gaimard's Rat-Kangaroos (*Hypsiprymnus gaimardi*) from Australia, presented by Mr. Walter Howker; a Cuckoo (*Cuculus canorus*), British, presented by Mr. Stacy Marks, R.A., F.Z.S.; two Red-billed Tree Ducks (*Dendrocygna autumnalis*) from America, presented by Mr. Keswick; two White-faced Tree Ducks (*Dendrocygna viduata*) from Brazil, presented by Captain C. A. Findlay, R.N.R.; a Common Viper (*Vipera berus*), British, presented by Mr. J. Sargeant; two White-headed Sea-Eagles (*Haliaetus leucocephalus*) from North America, deposited; a Burchell's Zebra (*Equus burchelli* ♂), a Derbian Wallaby (*Halmaturus derbianus*), three Common Night Herons (*Nycticorax griseus*), bred in the Gardens.

OUR ASTRONOMICAL COLUMN.

THE CAPTURE THEORY OF COMETS.—The last three numbers of the *Bulletin Astronomique* (April-June) have contained papers by M. L. Schulhof, "Sur les Grandes Perturbations des Comètes Périodiques," which place beyond doubt the idea that the periodic comets of our system are captured by the perturbing action of planets. The main object of the research was to develop the relations existing between the elements of the comet's orbit before and after its entrance within the sphere of activity of the disturbing planet. With the criteria obtained, and some results previously formulated by M. Tisserand, it is possible to decide the question as to the identity of two comets of which the time of revolution of one is known, even when the comet is believed to have passed several times within Jupiter's sphere of activity between two apparitions. This result is of the highest importance, for it is only by such means that individual comets can be identified. They cannot be recognized by their appearance, as they possess no peculiar characteristic that can be telescopically observed.

M. Schulhof suggests that, in the light of recent work, periodic comets should not now be classified according to their aphelion distances, but arranged in groups the mean aphelion distance of which approximates to the length of the semi-major axis of one or other of the planets. Such a division has been made for comets having periods between 10 and 10,000 years. From the tabulated results, it appears that four comets have aphelion distances which differ but little from the aphelion distance of Mercury. The Venus group numbers seven, the earth's group ten. Mars possesses four comets, and Jupiter twenty-three. Saturn has a family of nine, Uranus eight, and Neptune five.

WOLF'S PERIODIC COMET (*b* 1891).—The following ephemeris is from one given by Prof. Berberich in *Edinburgh Circular* No. 17. From *Astronomische Nachrichten*, No. 3042, it appears that Dr. Spitalier observed this comet on May 2; that is, before Prof. Barnard. The brightness on the date (May 4) of rediscovery by the latter observer has been taken as unity.

Ephemeris for Berlin Midnight.

The comet is now in Pisces, and in the beginning of September will pass through the Pleiades. M. Bigourdan, of Paris Observatory, observed it on June 12, and remarked that it was "une nebulosité ronde, d'environ 20" de diamètre, de grandeur 13·3."

YORUBA AND GAZALAND.

AT the meeting of the Royal Geographical Society, on Monday, two papers were read: one by Mr. Alvan Millson, on the Yoruba country, West Africa, and the other by Mr. Denis Doyle, on a journey in Gazaland, in South-East Africa.

The ancient kingdom of Yoruba may be taken as one of the most interesting of the great tribal divisions of West Africa, between the Gold Coast and the Niger.

Landing at Lagos, the only natural harbour on a thousand miles of coast, a narrow entrance with a 15-feet bar leads into the intricate chain of waterways which extends, with few and slight interruptions, for 500 miles from the Volta river to the Benin branch of the Niger Delta. From the east and west, from the Benin river and the waters of the Dahomian frontier, the coast of the gulf is backed by intersecting channels of fresh water flowing steadily from either hand towards the Lagos outlet. In many places these narrow and brimming channels are separated from the onslaught of the Atlantic rollers by no more than five or six level yards of shifting sand; the spray from the ocean drifts over them, and the roar of the surf is heard by the native as he glides over their calm surface in his fragile canoe. These so-called "lagoons of the Bight of Benin" form but a small portion of the littoral river systems of West Africa; for from Cape Palmas to Cape Three Points the long Kroo coast is lined by inland waters for the greater part of 300 miles, and beyond the rocky spurs of the beautiful Gold Coast the Dahomian shores have the same remarkable formation. At right angles to this network of channels numerous rivers flow down from the uplands of the interior, carrying in their rapid streams vast quantities of sand and mud with which they busily build out the land. At first sight it seems strange that so many and such powerful streams, flowing strongly towards the sea should suddenly be turned aside from their courses by so narrow and fragile a barrier of shifting sand. To the influence of the sheltering headlands which jut out towards the south; to the rapid Guinea current which tears away the face of their rocky shores and hurries towards the east a ceaseless stream of sand; to the almost tideless ocean, and the absence of high winds, for the strength and duration of a West African tornado are but slight as compared with the hurricanes of the West Indies or the gales of our stormy coast; and above all to the enormous growths of floating papyrus and water-grass which line the inner banks of the lagoons, and prevent the swollen waters from breaking through into the ocean, are due the formation and continual development of this strange delta system. For these rivers are in most instances choked for many miles by a floating papyrus-sod bound together by wild water-figs and palm-wine palms (*Raphia vinifera*), and when the floods come down from the interior great masses of this floating vegetation are torn away and carried down to the lagoons and onwards towards the sea. Hundreds of acres of these grass islets are annually carried down from each of these rivers, and are driven against the banks of the littoral lagoons, where they lodge and grow, and eventually become anchored in their places by more permanent vegetation. In this manner the lagoon sides are padded for hundreds of yards, and even, in some instances, for two or three miles in depth on either hand, and their banks are protected from the wash of the current and the weight of the accumulated waters. By this means the frail barrier of sea-sand is strengthened, and the inland waters, although they frequently rise to a height of 5 to 6 feet above the sea-level, are effectually prevented from bursting through their banks. Not only are these growths a permanent protection to the land, but by their very nature, floating as they do on the surface of the water, they rise and fall with the floods, and are always ready with their assistance at the right time and place. Were all the rivers which feed the lagoons freed from their natural obstructions, as is the case with the Ogun river near Lagos, the interior to a distance of from thirty to seventy miles would be thrown open to commerce, and the wonderful system of inland navigation which fosters the coast traffic would be still further developed.

Mr. Millson went on to describe a journey from the coast to the interior, the country rising from terrace to terrace. He then spoke at some length of the Yoruba people and country.

About eighty miles from the coast, at Oda Ona Kekere, the dense forest suddenly gives place to open cultivated land, and a densely peopled country. Some three miles to the north of Odo Ona Kekere, from the crest of a rising in the undulating land the great city of Ibadan—the London of Negroland—comes full in view, extending for over six miles from east to west, and for more than three from north to south. Surrounded by its farming villages, 163 in number, Ibadan counts over 200,000 souls, while within the walls of the city itself at least 120,000 people are gathered. Its sea of brown roofs covers an area of nearly 16 square miles, and the ditches and walls of hardened clay which surround it are more than 18 miles in circumference. Its houses are built round courtyards with a single entrance, and form in themselves no mean defence against native inroads. Their walls of thick "adobe" are blank on the outer face, and the thatched roofs are made of a light covering of palm leaves and grass in order to avoid the danger of extensive conflagrations. In the winding rocky streets which intersect these large compounds in every

Digitized by Google

direction, are countless market booths and occasional market places, where the inhabitants can purchase native produce, food, and European luxuries. In the same way, by the sides of the country roads, are built at irregular intervals varying from one to six miles, long low sheds close by some well or running water, where the farm women sit and "make their market." In the farms which extend throughout the country from horizon to horizon as one journeys through it, save where the land is too poor, or the fear of war has desolated the neighbourhood, can be heard the crowing of cocks, the barking of dogs, the shrill laughter of children, and the vociferous clamour of native homestead gossip. For among natives, as among seafaring folk at home, a hundred yards or so is no impediment to polite conversation. From this custom arises the disadvantage that the voices of the people being naturally pitched for distant communication cannot readily be restrained or focussed for nearer ranges of social intercourse. The consequent turmoil and shrill cries are apt at first to unsettle the nerves of an inexperienced traveller, but a few weeks' residence in the country not only accustoms one to their manner of speech, but inures one's system to the sudden shock of their sonorous voices.

Northward from Ibadan, which may be described as the centre of the chief military and commercial power in Yoruba, two days' journey—about 40 miles—through many villages, and a landscape dotted far and near with oil-palms (*Elæis guineensis*) along a road thronged with travellers, brings one to the capital of central Yoruba, Oyo (Awyaw). On leaving Ibadan, Mr. Millson passed, in the course of a morning's march, over 4700 men, women, and children, hurrying into the great city from the farm villages with loads of maize, beans, yams, yam flour, sweet potatoes, fowls, pigs, ducks; or driving cattle, sheep, and goats; or mounted on small native horses which amble quickly along under the combined influence of an Arab ring bit and an armed spur which leaves its traces in deep scores along the flanks of the poor animals. Far and wide the land has for generations, and indeed for centuries, been cultivated by these industrious natives. The hatchet, the fire and the hoe, have removed all traces of the original forest, save indeed where a dark trail of green across the landscape shows where the valley of some narrow watercourse or larger river is hidden among trees. For two or three years at most the land is allowed to lie fallow, while for three or four years double or treble crops are raised with no further cultivation than an occasional scrape with a hoe, and during its fallow time no further care is taken of it than to let a rank growth of reedy grass spring up some 6 or 8 feet in height. Among this grass can be seen the seedlings and young plants of a new forest, which would rapidly take possession were the land to be permanently deserted. In spite of this careless and exhausting method of cultivation the crops maintain an excellent average, and the same plot of ground serves for generations to support its owners.

Mr. Doyle, who accompanies King Gungunhana's two envoys to this country, described his journey from the Mashonaland plateau down through Gazaland to the mouth of the Limpopo. At first the journey was through a broken plateau country, rising to 5000 feet and over, and well adapted for farming operations. After fourteen days' travel, the country suddenly drops from a level of 4000–5000 feet to 860 feet above sea-level. For many miles the altitude was no more than 300 feet, and as it was the rainy season when Mr. Doyle and his companions passed through, they found the country almost entirely a swamp. The actual distance travelled was between 700 and 800 miles, which was traversed in forty-six days.

THE CONDITION OF SPACE.

THE question of the condition of inter-planetary space, with special reference to the possibility that it offers a resistance to the passage of the heavenly bodies, has for long occupied the attention of astronomers, but is even yet far from receiving a satisfactory or definite solution. Three hypotheses seem to be more or less in vogue:—

(1) That it is filled with "ether," differing entirely in its properties from ordinary matter, and offering no resistance to the passage of solid or gaseous bodies. Radiant energy is transmitted by the vibratory motion of the ether, and possibly also the force of gravitation is transmitted by a rotatory motion, though, as Laplace points out, the velocity of the gravitation must be at least 7,000,000 times that of light.

(2) That it is filled with an ether more analogous to ordinary matter, which offers resistance, or with a highly rarefied gaseous medium similar in constitution to our atmosphere.

(3) That it is filled with ether, through which innumerable solid bodies of comparatively small size fly singly or in swarms. When they encounter one another, a gas, or a planet, they become luminous, and present the appearance of fireballs, meteorites; shooting-stars, meteors; comets, meteoric swarms, meteoric dust gives rise to the phenomenon of the aurora borealis. This theory has recently been much extended and admirably advocated by Prof. J. Norman Lockyer, in "The Meteoritic Hypothesis."

If the first hypothesis be true, and space offers no resistance to the passage of the planets, Laplace has shown (*Mém. Acad. des Sciences*, 1784) that any change in their orbits will be periodic, or, in other words, that, with only slight variations from time to time, the present condition of the solar system will continue indefinitely.

If the second hypothesis be true, the resistance, however slight it may be, will tend to retard the motion of the planets. In the case of the earth the friction between the outer layers of the atmosphere and the medium will retard the rotation of the earth, and increase the length of the day. There will also be resistance to the motion of the earth in her orbit, which will tend to decrease the velocity, and therefore to lengthen the year; but on the other hand, if the tangential velocity be decreased while the attraction of the sun remains the same, the earth will fall towards the sun, the mean distance will decrease, and therefore the time of revolution will be shortened.

If the third hypothesis be true, the rain of meteorites will have no effect on the rotation of the earth, but will tend to lessen the orbital velocity.

Laplace has discussed some consequences of the second hypothesis in "Mécanique Céleste," vii. 6, on secular variations in the movements of the moon and earth which might be produced by the resistance of an etherial medium spread round the sun. He assumes that the density of the medium is a function of the distance from the sun, and that the resistance varies as the square of the velocity. He concludes that the acceleration produced by the resistance of a fluid ether on the mean motion of the moon is, up to "the present time," insensible; and that the acceleration produced by the same ether on the motion of the earth would be less than 1/100 that caused to the motion of the moon. These results are extended to other planets and to comets in x. 7, where it is shown that the distance at perihelion remains unchanged, and the only alteration in the orbit is a decrease in the length of the major axis and in the eccentricity.

The question is discussed from a mathematical point of view in several text-books (*e.g.* Tait and Steele, "Dynamics of a Particle," pp. 279, 379), but in all cases the mathematics are somewhat difficult, and various assumptions have to be made to render the solution possible.

In the case of the earth, if the resistance of the medium be small, the orbit may be considered to be circular, more especially as it follows from Laplace's results that the error introduced decreases with the time, since the orbit becomes more nearly circular. The following brief abstract of the popular treatment suggested by G. A. Hirn in his "Constitution de l'Espèce Céleste," pp. 104–108, with the substitution of English values, and the extension of the results to the meteoric hypothesis, may be not without interest at the present time.

Many of the data are so uncertain, that the rough approximations by which mathematical difficulties are avoided probably produce no great loss of arithmetical accuracy in the results.

The *vis viva* of the earth at the end of any period is equal to the *vis viva* at the commencement of the period, less the *vis viva* lost owing to the resistance of the medium, and increased by the *vis viva* due to the fall towards the sun. Transposing and dividing by M/2—

$$v_r^2 = v_o^2 + v_s^2 - v_f^2.$$

Writing S for the attraction of the sun, and resolving along the radius vector A—

$$v_o^2/A_o = S, \quad \therefore v_o^2 = SA_o.$$

After a time t,

$$v_t^2/A = S\frac{A_o^2}{A_t^2}, \quad \therefore v_t^2 = SA_o^2/A_t.$$

Digitized by Google

The acceleration towards the sun is expressed by

$$\frac{d^2A}{dt^2} + S \cdot \frac{A_o^3}{A_t^2} = 0;$$

and integrating,

$$v_r^2 = 2SA_o\left(\frac{A_o}{A_t} - 1\right).$$

Substituting and reducing,

$$v_r^2 = v_o^2\left(\frac{A_o}{A_t} - 1\right).$$

Hence the *vis viva* lost, owing to the resistance of the medium, is one-half of the *vis viva* gained by falling through $A - A_t$ towards the sun, and the presence of a very slightly resisting medium *increases* the velocity of the earth in its orbit. This increase is easily expressed, since, by Kepler's third law, we may replace $(A_o/A_t)^3$ by $(T/T_t)^2$, where T_oT_t are the periodic times at the beginning and end of the period;

$$\therefore v_r^2 = v_o^2\left\{\left(\frac{T_o}{T_t}\right)^{\frac{2}{3}} - 1\right\}.$$

But the *vis viva* lost owing to the resistance is equal to the work done in forcing the sphere against the resistance of the medium through the distance passed over by the earth during the time. We may assume for simplicity that during the last 2000 years the length of the year has shortened by five seconds; and since the change in the radius vector would be very small, that $A = 23300a$, where a is the radius of the earth, and hence that the distance through which the earth has passed is $\pi 23300a\ 2000$.

M. Hirn, by theory and experiment, shows considerable reason for believing that the formula of Hutton, for the resistance of a medium in terms of the density δ, gives a result not far from the truth. Hence

$$0451 \times (\pi a^2)^{1\cdot1} \times \delta \times v_o^2 \times 2\pi\ 23300a\ 2000 = \frac{Mv_o^2}{2}\left\{\left(\frac{T_o}{T_t}\right)^{\frac{2}{3}} - 1\right\},$$

where $$\left(\frac{T_o}{T_t}\right)^{\frac{2}{3}} - 1 = \left(1 + \frac{5}{31558150}\right)^{\frac{2}{3}} - 1 = \frac{1}{9467445}.$$

$$\therefore \frac{1}{\delta} = (\log^{-1}14\cdot32278) \times ga^{\cdot2}/\Delta,$$

where Δ is the absolute mass of unit volume of the material of the earth.

$$\therefore \frac{1}{\delta} = 5\cdot64 \times 10^{14} \text{ cubic feet.}$$

M. Hirn further points out that this decrease of five seconds in the length of the year during a period of 2000 years would be accompanied by a change in the longitude of the earth of more than 205", an amount quite inadmissible since the time of Hipparchus, while the above results have shown that, to produce an acceleration so small as this, the medium must have a rarity such that one pound occupies 564 billions of cubic feet. And the volume occupied by a pound of the gas very nearly varies inversely as the number of seconds gained in the periodic time.

When we pass on to consider the retardation caused by the action of meteorites, we lose the guidance of M. Hirn, but are able to refer for data to Prof. Lockyer's treatise.

About 30 miles, or 158,400 feet per second, may be taken as the average velocity of meteorites (p. 68). Suppose the earth at rest, and struck by a meteorite weighing one pound with this velocity, the *vis viva* of the blow would be $\frac{1}{2g}(158400)^2 = 3\cdot98 \times 10^8$ absolute foot-pounds (p. 64).

But the earth is moving in its orbit with a velocity of 18·4 miles, or 97,130 feet per second; hence, of every three meteorites we may presume that two strike the front, and one the back hemisphere. Further, the velocity of the earth is, in the one case, to be added to, and, in the other case, subtracted from, the velocity of the meteorites. Again, we may assume that the earth is struck about equally all over each hemisphere, and that, owing to its attraction, the blows are vertical, and hence that the energy added and subtracted in each hemisphere in the direction of the motion of the earth is one-half of the total *vis viva*, or for three meteorites, each weighing a pound,

$$\frac{1}{2g}\{(158400 + 97130)^2 - \tfrac{1}{2}(158400 - 97130)^2\}$$
$$= 4\cdot58 \times 10^9 \text{ foot-pounds.}$$

Suppose that a meteorite weighing one pound has the specific heat 0·2, which is about double of that of iron; to raise it from −270° C. to 2000° C., 454 units of heat are required, which are equivalent to about $454 \times 44758 = 2 \times 10^7$ absolute foot-pounds of work—a quantity which may be neglected, in comparison with the total *vis viva* of the meteorite.

The weight of meteorites varies from tons to small specimens (p. 19), and hence we must assume an average weight of μ pounds. According to Newcomb, 20,000,000 meteorites a day enter our atmosphere (p. 69). We may again assume that the action has continued for 2000 years, and caused a shortening in the periodic time of five seconds.

The *vis viva* of the impacts,

$$\mu \times 4\cdot58 \times 10^9 \times \frac{20000000}{3} \times 365 \times 2000,$$

must be equal to the *vis viva* lost by the earth,

$$\tfrac{1}{2}Mv_o^2\left\{\left(\frac{T_o}{T_t}\right)^{\frac{2}{3}} - 1\right\}, \text{ which is } \frac{4\pi a^3 \times 10\cdot86 \times (97130)^2}{6 \times 9467445};$$

$$\therefore \mu = \frac{1\cdot95 \times 10^{33}}{1\cdot115 \times 10^{19} \times 2000 \times 9467445}$$
$$= 9240 \text{ pounds, or over 4 tons.}$$

In this case, also, the average mass of the meteorites varies inversely as the shortening of the periodic time. Thus, if the average weight of meteorites is 9 pounds, the shortening would be only 0·005 second—an amount probably inappreciable.

SYDNEY LUPTON.

THE FLOWERS OF THE PYRENEES AND THEIR FERTILIZATION BY INSECTS.[1]

THE observations described in this work were made in the Vallée de Luz (Hautes Pyrénées, France), in August 1889 and June 1890, between 900 and 2200 metres altitude. The author has noticed 1801 visits, brought by 507 different insects to 261 different flowers. In the list of the visits, date and altitude are always noted, and in many cases particulars are given about the special habits of insects in visiting flowers. Many of the mentioned insects were not before seen visiting flowers.

The contrivances by which the flowers are fertilized are described for the following species: *Merendera Bulbocodium*, *Asphodelus albus* (lepidopterophilous, proterogynous), *Hyacinthus amethystinus* (proterandrous, adapted to long-tongued bees), *Iris pyrenaica*, *Antirrhinum sempervirens*, *Linaria origanifolia* (adapted to bees, with special entrance for Lepidoptera or Bombylidæ), *Linaria pyrenaica*, *Horminum pyrenaicum* (gynomonœcious), *Scutellaria alpina* (adapted to long-tongued bees, with special entrance for Lepidoptera), *Teucrium pyrenaicum* (adapted to bees, with entrance for Lepidoptera), *Dianthus monspessulanus* (lepidopterophilous), *Alsine* sp., *Alsine verna*, *Aconitum pyrenaicum* (resembles the *A. lycoctonum*), *A. Anthora*, *Aquilegia pyrenaica*, *Brassica montana* (lepidopterophilous), *Roripa pyrenaica*, *Reseda glauca*, *Geranium cinereum* (proterandrous, gynodiœcious), *Saxifraga longifolia* (proterandrous), *Potentilla alchemilloides*, *Potentilla fragariastrum*.

Some details are given about the construction of the flowers in the following species: *Cirsium eriophorum*, *C. monspessulanum*, *Carduus medius*, *C. carlinoides*, *Centaurea Scabiosa*, *Gnaphalium Leontopodium*, *Angelica pyrenæa*. Almost all those species are illustrated (94 figures), and the explanation of each figure is given in French and in Dutch.

General conclusions:—The relative number of hemitrope Diptera (Syrphidæ, Conopidæ, and Bombylidæ), of allotrope Hymenoptera (all Hymenoptera except the bees), of long-tongued not-social bees and of Coleoptera decreases with increasing altitude. The hemitrope Diptera (all Diptera except those mentioned above) become on the contrary relatively more numerous with increasing altitude; this seems to be also the case with the social long-tongued bees (represented in the Pyrenees by *Bombus* and *Psithyrus*). Müller came to the same conclusions about the influence of altitude upon the same groups of insects in the Alps.

[1] "De Pyreneeënbloemen en hare bevruchting door insecten," 226 pages, with five plates, a French *résumé*, and the explanation of the plates in French. In *Botanisch Jaarboek*, iii., 1891, published by the Botanical Society Dodonæa, in Ghent, Belgium).

Digitized by Google

On the other hand, Müller noticed that in the Alps the relative number of Lepidoptera increases, of hemitrope Hymenoptera (short-tongued bees) decreases in the higher parts of the mountains. The influence of altitude upon those two groups of insects is not evident in the Pyrenees.

The Lepidoptera—which in the Alps, according to Müller, are very numerous—are much less numerous in the Pyrenees. All the allotrope insects (Coleoptera, allotrope Diptera, and allotrope Hymenoptera) are relatively more numerous in the Pyrenees than in the Alps. The hemitrope Hymenoptera (short-tongued bees) are somewhat more numerous in the Pyrenees than in the Alps; the hemitrope Diptera (Syrphidæ, Conopidæ, and Bombylidæ) are almost equally represented in both the mountains. The eutrope Hymenoptera (long-tongued bees) seem to be equally numerous in the Pyrenees and in the Alps; in both countries, the humble-bees are predominant, and the not-social long-tongued bees are scarce.

The following table will enable students to compare the flora of the Pyrenees with that of the Alps:—

	Pyrenees.			Alps.	
	Species.	Per cent.		Species.	Per cent.
Pollen flowers (class Po) ...	12	(4·6)	...	14	(3·3)
Fl. with free-exposed honey (class A)	34	(13·0)	...	42	(10·1)
Fl. with partially concealed honey (AB)	45	(17·2)	...	61	(14·6)
Fl. with quite concealed honey (B).....	37	(14·1)	...	66	(15·3)
Associated flowers with quite concealed honey (B′)	48	(18·4)	...	84	(20·2)
Flowers adapted to bees (Bb)	73	(27·9)	...	110	(26·4)
Flowers adapted to Lepidoptera (Vb)	12	(4·6)	...	39	(9·3)

The allotrope flowers (Po, A, AB) are relatively more numerous, the lepidopterophilous flowers (Vb) are less numerous in the Pyrenees than in the Alps; we have seen that the same differences exist for the corresponding groups of insects.

The hemitrope flowers (B, B′) are a little more numerous in the Alps than in the Pyrenees; the contrary occurs with the hemitrope insects. There is here accordingly no concordance in the geographical distribution between flowers and insects; but the hemitrope insects are not so constant in the choice of their flowers as the allotrope insects and the Lepidoptera; their influence upon the distribution of the corresponding flowers is therefore not so great as that of the two latter groups. The class Bb and the long-tongued bees are nearly equally represented in both the mountains. The parallelism which occurs between the relative abundance of the classes Po, A, AB, Bb, and Vb, and the relative abundance of corresponding insects, agrees very nicely with the theory of flowers.

It may be observed that in the Pyrenees, with reference to the biological floral organization, the Choripetalæ are, on the whole, on a lower level than the Sympetalæ. Only a small number of Monocotyledoneæ could be observed.

University, Ghent. J. MACLEOD.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The Council of the Senate have appointed Mr. E. Hill, of St. John's College, to be a governor of Woodbridge School, under the new scheme.

The Harkness Scholarship in Geology and Palæontology has been awarded to Herbert Kynaston, of King's College.

Mr. A. A. Kanthack has been elected to the John Lucas Walker Studentship in Pathology, vacated by the election of Mr. J. G. Adami to a Fellowship at Jesus College. Mr. Kanthack is at present in India as a member of the Leprosy Commission.

The managers of the John Lucas Walker Fund have made a grant of £60 to Mr. E. H. Hankin, Fellow of St. John's, for the purchase of bacteriological apparatus required for his researches.

I. H. Burkill, of Caius College, has been appointed Assistant Curator of the Herbarium.

Prof. Ewing advertises for a demonstrator in mechanism, who has had a workshop training in mechanical engineering. The salary is £150 a year.

The annual report of the Local Lectures Syndicate, published in the *University Reporter* of June 23, records a large amount of useful work in so-called University extension. The number of courses given in 1890-91 was 135, with an average attendance of 10,947. The average attendance at the classes held after lecture was 4916, the number of weekly papers sent in 2266, and the number of candidates examined for certificates 1547. The following passages refer to a fresh departure of considerable interest, and of far-reaching possibilities in the future:—

"The grant for technical education which has been put at the disposal of the County Councils has led to an extension of the work of the Syndicate, and it seems not improbable that if a grant of this nature is made permanent a considerable demand will be made upon their staff of lecturers. In Devonshire they have provided at the request of the County Council a Lecturer on Chemistry and a Lecturer on Mechanics, in each case with special reference to applications to agriculture. The lectures in chemistry were given at six centres, those in mechanics at five. The average weekly attendance was—at lectures about 40, at classes about 25, at each centre. In all, 64 students presented themselves for examination, of whom 44 passed, 14 obtaining distinction. The audience comprised a number of boys from elementary and secondary schools, and some working men and farmers and schoolmasters, in addition to the usual mixed audience. The lectures were of necessity arranged rather hurriedly, without sufficient time for the local authorities to complete their organization, and they can only be regarded as an experiment. The Syndicate have reason to think that the experiment has been as successful as under the circumstances could be expected. . . .

"Having regard to the probability of a considerable demand for lecturers in connection with the County Councils, the Syndicate have added to their list several new lecturers whose attainments mark them out as suitable for this work. And in order that the lecturers may have practical acquaintance with the applications of their science to the uses of agriculture, the Syndicate have arranged that they should pay visits to farms of various characters and to the experimental farm at Woburn. These visits are paid under the experienced superintendence of Mr. H. Robinson, of Downing College, the assistant to the Professor of Chemistry. Mr. Robinson conducts also a course of laboratory work with the lecturers, with special reference to agricultural investigations. The Syndicate desire to express their grateful sense of the help which Prof. Liveing and Mr. Robinson have so liberally given. The provision of teaching and guidance in Cambridge for the scientific study of subjects connected with agriculture appears to the Syndicate to be so important for the training of students who may become lecturers on their staff, that they will endeavour to secure a continuance of this assistance, and are prepared to devote a portion of their funds to the purpose."

The *Ordo Senioritatis* for the year shows that 6 D.Sc. degrees have been conferred, 19 M.D. degrees, 72 M.B., and 70 B.C. These figures bespeak the steady growth of the faculties of science and medicine, the numbers in medicine being larger than in any previous year.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, June 11.—"On Electrical Evaporation." By William Crookes, F.R.S.

It is well known that when a vacuum tube is furnished with internal platinum electrodes, the adjacent glass, especially near the negative pole, speedily becomes blackened, owing to the deposition of metallic platinum. The passage of the induction current greatly stimulates the motion of the residual gaseous molecules; those condensed upon and in the immediate neighbourhood of the negative pole are shot away at an immense speed in almost straight lines, the speed varying with the degree of exhaustion and with the intensity of the induced current. Platinum being used for the negative pole, not only are the gaseous molecules shot away from the electrode, but the passage of the current so affects the normal molecular motions of the metal as to remove some of the molecules from the sphere of attraction of the mass, causing them to fly off with the stream of gaseous molecules proceeding from the negative pole, and to adhere to any object near it. This property was, I believe, first pointed out by Dr. Wright, of Yale College, and some interest-

Digitized by Google

experiments are described by him in the *American Journal ience and Arts*.[1] The process has been much used for the duction of small mirrors for physical apparatus.

his electrical volatilization or evaporation is very similar to nary evaporation by the agency of heat. Cohesion in solids es according to physical and chemical constitution; thus every l of solid matter requires to be raised to a certain temperature re the molecules lose their fixity of position and are rendered id, a result which is reached at widely different temperatures.

ae consider a liquid at atmospheric pressure—say, for ance, a basin of water in an open room—at molecular ances the boundary surface between the liquid and the super-umbent gas will not be a plane, but turbulent like a a stormy an. The molecules at the surface of the liquid dart to and rebound from their neighbours, and fly off in every direction. ir initial velocity may be either accelerated or retarded, rding to the direction of impact. The result of a collision drive a molecule in such a direction that it remains part and cel of the liquid; on the other hand, it may be sent upwards hout any diminution of speed, and it will then be carried ond the range of attraction of neighbouring molecules and fly into and mingle with the superincumbent gas. If a molecule the liquid has been driven at an angle with a velocity not icient to carry it beyond the range of molecular attraction of liquid, it may still escape, since, in its excursion upwards, a eous molecule may strike it in the right direction, and its porary visit may be converted into permanent residence.

The intrinsic velocity of the molecules is intensified by heat l diminished by cold. If, therefore, we raise the temperature the water without materially increasing that of the surround-air, the excursions of the molecules of the liquid are rendered ger and the force of impact greater, and thus the escape of ecules into the upper region of gas is increased, and we say evaporation is augmented.

f the initial velocities of the liquid molecules can be eased by any other means than by raising the temperature, hat their escape into the gas is rendered more rapid, the ult may be called "evaporation" just as well as if heat had n applied.

Hitherto I have spoken of a liquid evaporating into a gas; the same reasoning applies equally to a solid body. But ast a solid body like platinum requires an intense heat to ble its upper stratum of molecules to pass beyond the sphere ttraction of the neighbouring molecules, experiment shows a very moderate amount of negative electrification super-s sufficient energy to enable the upper stratum of metallic ecules to fly beyond the attractive power of the rest of the al.

f a gaseous medium exists above the liquid or solid, it vents to some degree the molecules from flying off. Thus h ordinary and electrical evaporation are more rapid in a uum than at the ordinary atmospheric pressure.

have recently made some experiments upon the evaporation different substances under the electric stress.

Evaporation of Cadmium.—A U-shaped tube was made, ing a bulb in each limb. The platinum poles were at the emities of each limb, and in each bulb was suspended from mall platinum hook a small lump of cadmium, the metal ing been cast on to the wire. The wires were each weighed h and without the cadmium. The tube was exhausted, and lower half of the tube was inclosed in a metal pot containing affin wax, the temperature being kept at 230° C. during the tinuance of the experiment. A deposit around the negative e took place almost immediately, and in five minutes the bulb rounding it was opaque with deposited metal. The positive e with its surrounding luminosity could be easily seen the le time. In thirty minutes the experiment was stopped, and n all was cold the tube was opened and the wires weighed in. The results were as follows:—

	Positive pole.	Negative pole.
ginal weight of cadmium	9·34 grs.	9·38 grs.
ght after experiment	9·25 ,,	1·86 ,,
dmium volatilized in 30 mins. ...	0·09 ,,	7·52 ,,

Finding that cadmium volatilized so readily under the action the induction current, a large quantity, about 350 grs., of pure metal was sealed up in a tube, and the end of the tube taining the metal was heated to a little above the melting-point; the molten metal being made the negative pole, in a few hours the whole quantity had volatilized and condensed in a thick layer on the far end of the tube, near, but not touching, the positive pole.

Volatilization of Silver.—Silver was the next metal experimented upon. The apparatus was similar to that used for the cadmium experiments. Small lumps of pure silver were cast on the ends of platinum wires, and suspended to the inner ends of platinum terminals passing through the glass bulb. The platinum wires were protected by glass, so that only the silver balls were exposed. The whole apparatus was inclosed in a metal box lined with mica, and the temperature was kept as high as the glass would allow without softening. The apparatus was exhausted to a dark space of 3 mm., and the current was kept on for 1½ hours. The weights of silver, before and after the experiment, were as follows:—

	Positive pole.	Negative pole.
Original weight of silver ...	18·14 grs.	24·63 grs.
Weight after the experiment ...	18·13 ,,	24·44 ,,
Silver volatilized in 1½ hours ...	0·01 ,,	0·19 ,,

In this tube it was not easy to observe the spectrum of the negative pole, owing to the rapid manner in which the deposit obscured the glass. A special tube was therefore devised, of the following character:—A silver rod was attached to the platinum pole at one end of the tube, and the aluminium positive pole was at the side. The end of the tube opposite the silver pole was rounded, and the spectroscope was arranged to observe the light of the volatilizing silver "end on." In this way the deposit of silver offered no obstruction to the light, as none was deposited except on the sides of the tube surrounding the silver. At a vacuum giving a dark space of about 3 mm. from the silver, a greenish-white glow was seen to surround the metal. This glow gave a very brilliant spectrum. The spark from silver poles in air was brought into the same field of view as the vacuum glow, by means of a right-angled prism attached to the spectroscope, and the two spectra were compared. The two strong green lines of silver were visible in each spectrum; the measurements taken of their wave-lengths were 3344 and 3675, numbers which are so close to Thalén's numbers as to leave no doubt that they are the silver lines. At a pressure giving a dark space of 2 mm. the spectrum was very bright, and consisted chiefly of the two green lines and the red and green hydrogen lines. The intercalation of a Leyden jar into the circuit does not materially increase the brilliancy of the lines, but it brings out the well-known air lines. At this pressure not much silver flies off from the pole. At a higher vacuum the luminosity round the silver pole gets less and the green lines vanish. At an exhaustion of about one-millionth of an atmosphere the luminosity is feeble, the silver pole has exactly the appearance of being red-hot, and the volatilization of the metal proceeds rapidly.[1]

If, for the negative electrode, instead of a pure metal such as cadmium or silver, an alloy was used, the different components might be shot off to different distances, and in this way make an electrical separation—a sort of fractional distillation. A negative terminal was formed of clean brass, and submitted to the electrical discharge *in vacuo*; the deposit obtained was of the colour of brass throughout, and on treating the deposit chemically I could detect no separation of its component metals, copper and zinc.

A remarkable alloy of gold and aluminium, of a rich purple colour, has been kindly sent me by Prof. Roberts-Austen. Gold being very volatile in the vacuum tube, and aluminium almost fixed, this alloy was likely to give different results from those yielded by brass, where both constituents fly off with almost equal readiness. The Au-Al alloy had been cast in a clay tube, in the form of a rod 2 cm. long and about 2 mm. in diameter.

[1] Third Se ol. xii. p. 49, January 1877; and vol. xiv. p. 169,

[1] Like the action producing volatilization, the "red heat" is confined to the superficial layers of molecules only. The metal instantly assumes, or loses, the appearance of red heat the moment the current is turned on or off, showing that, if the appearance is really due to a rise of temperature, it does not penetrate much below the surface. The extra activity of the metallic molecules necessary to volatilize them is, in these experiments, confined to the surface only, or the whole mass would evaporate at once, as when a metallic wire is deflagrated by the discharge of a powerful Leyden jar. When this extra activity is produced by artificial heat one of the effects is the emission of red light; so it is not unreasonable to imagine that when the extra activity is produced by electricity the emission of red light should also accompany the separation of molecules from the mass. In comparison with electricity, heat is a wasteful agent for promoting volatilization, as the whole mass must be raised to the requisite temperature to produce a surface action merely; whereas the action of electrification does not appear to penetrate much below the surface.

Digitized by Google

to the current. By dividing the numbers so obtained by the specific gravity of the metal, the following order is found:—

Palladium	9·00	Copper	[illegible]
Silver	7·88	Platinum	[illegible]
Tin	7·76	Nickel	[illegible]
Lead	6·61	Iron	[illegible]
Gold	5·18	Iridium	[illegible]
Cadmium	3·72		

Aluminium and magnesium appear to be practically non-volatile under these circumstances.

The order of metals in the table shows at once that electrical volatility in the solid state does not correspond with the order of melting-points, of atomic weights, or of any other well-known constant. The experiment with some of the [illegible] metals was repeated, and the numbers obtained do not vary materially from those given above, showing that the order is not likely to be far wrong.

It is seen in the above table that the electrical volatility of silver is high, while that of cadmium is low. In the two experiments, where cadmium and silver were taken, the cadmium negative electrode in 30 minutes lost 7·52 grs., whilst the silver negative electrode in 1½ hours only lost 0·19 gr. This discrepancy is easily explained by the fact (already noted in the case of cadmium) that the maximum evaporation effect, or electrical disturbance, takes place when the metal is at the point of liquefaction. If it were possible to form a negative electrode of molten silver, then the quantity volatilized in a given time would be probably more than that of cadmium. Silver having proved to be readily volatile under the electric current, an experiment was tried with a view to procuring a larger quantity of the volatilized metal. A tube was taken having at one end a negative pole composed of a weighed number of fine wires of pure gold, and an aluminium pole at the other end.

The tube was exhausted and the current from the induction coil put on, making the gold brush negative; the resistance of the tube was found to increase considerably as the walls became coated with metal, so much so that, to enable the current to keep flowing, air had to be let in after a while, depressing the vacuum.

The weight of the brush before experiment was 35 [illegible] grs. The induction current was kept on the tube for 14½ hours. At the end of this time the tube was opened and the brush removed. It now weighed 32·5613, showing a loss of 2·9327 grs. When heated below redness the deposited film of gold was easily removed from the walls of the tube in the form of very fine dust.

After having been subjected to electrical volatilization the appearance of the residual piece of gold under the microscope using a ¼ inch object-glass, was very like that of electrically deposited metal, pitted all over with minute hollows.

This experiment on the volatilization of gold having proved good coherent films of that metal, a similar experiment was tried, using a brush of platinum as a negative electrode. Referring to the table it will be seen that the electrical volatility of platinum is much lower than that of gold, but it was thought that by making longer time a sufficient quantity might be volatilized to enable it to be removed from the tube.

The vacuum tube was exhausted to such a point as to give a dark space of 6 mm., and it was found, as in the case of gold, that as a coating of metal was deposited upon the glass the resistance rapidly increased, but in a much more marked degree. The residual gas in the tube apparently becoming absorbed as the deposition proceeded. It was necessary to let a little air into the tube about every 30 minutes, to reduce the vacuum. This appears to show that the platinum was being deposited in a porous spongy form, with great power of occluding the residual gas.

Heating the tube when it had become this way non-conducting liberated sufficient gas to depress the gauge of the pump and to reduce the vacuum so as to give a dark space of about 3 mm. This gas was not re-absorbed on cooling, but on passing the current for ten minutes the tube again refused to conduct, owing to absorption. The tube was again heated, with the liberation of gas, but much less than before, and this on cooling the whole was re-absorbed on cooling.

The current was kept on this tube for 25 hours; it was then opened, but I could not remove the deposited metal even

Digitized by Google

small pieces, as it was brittle and porous. Weighing the brush that had formed, the negative pole gave the following results:—

	Grains.
Weight of platinum before experiment	10·1940
,, ,, after experiment	8·1570
Loss by volatilization in 25 hours	2·0370

Another experiment was made similar to that with gold and platinum, but using silver as the negative pole, the pure metal being formed into a brush of fine wires. Less gas was occluded during the progress of this experiment than in the case of platinum. The silver behaved the same as gold, the metal deposited freely, and the vacuum was easily kept at a dark space of 6 mm. by the very occasional admission of a trace of air. In 20 hours nearly 3 grs. of silver were volatilized. The deposit of silver was detached without difficulty from the glass in the form of bright foil.

Chemical Society, June 4.—Mr. W. Crookes, F.R.S., Vice-President, in the chair.—The following papers were read:—The molecular refraction and dispersion of various substances in solution, by Dr. J. H. Gladstone, F.R.S. The paper is a continuation of that laid before the Society in March last, and deals with solid and gaseous substances that have been dissolved in water and other liquids for examination. The results are given in several tables. In the case of organic compounds, the theoretical and experimental numbers are frequently in close agreement. Hydrogen chloride, bromide, and iodide give figures for the molecular refraction and dispersion much higher than the sum of the hydrogen and halogen as determined from the paraffin compounds, and the values rise as the dilution becomes greater. Selenious and selenic acids afford optical values much less than what would be expected from the known values of their constituents. Metaphosphoric acid does the same. The data relating to solutions of salts and alkalies will afford material for a revision of the refraction equivalents of the different metals, and of the electro-negative elements with which they are combined. Ammonia, in contrast with the hydrides of chlorine, bromine, and iodine, appears to be uniform in its optical properties, whatever the strength of the solution. The refraction equivalents of cerium, didymium, and lanthanum were found about 12·4, 16·4, and 15·5 respectively. The molecular refraction for ClO_3 in its salts dissolved in water comes out at about 18·3, that for BrO_3 at 24·9, and for IO_3 at 33·8.—The nature of solutions is elucidated by a study of the densities, heat of dissolution, and freezing-points of solutions of calcium chloride, by S. U. Pickering. The curves representing these properties were examined in the same way as those for sulphuric acid, and similar conclusions are drawn—namely, that changes of curvature, which occur at certain points which are the same whatever property is examined represent the existence of hydrates in solution. The simplest hydrates indicated consist of $CaCl_2$ with 4, 7, and $8H_2O$; more complex hydrates also exist, as in the case of sulphuric acid.—Note on a recent criticism by Mr. Sydney Lupton of the conclusions drawn from a study of various properties of sulphuric acid solutions, by S. U. Pickering. Mr. Lupton (*Phil. Mag.*, xxxi. 418) applies a single parabolic equation to a portion of one of the author's sulphuric acid density curves, where a change of curvature was supposed to exist, and shows that it represents the results accurately if the experimental error is of a certain magnitude. This magnitude is between 1000 and 10,000 per cent. greater than the ascertained magnitude, and the equation represents all errors of like signs as grouped together. Such a representation cannot disprove the existence of the particular change of curvature under examination, still less that of the 101 others examined by the author. The hydrate on which Mr. Lupton considers that his investigation throws "very grave suspicion" happens to be the one which the author has isolated in the crystalline condition. In the discussion which followed, Prof. Ramsay doubted the validity of Mr. Pickering's methods of differentiating his curves. His own experience was that it was impossible to obtain results nearer than 2 or 3 per cent. to the truth. Dr. Armstrong said that he was prepared to believe in the existence of hydrates in solution, but could not imagine that the 102 breaks in the sulphuric acid curves, for example, could be interpreted as evidence of as many distinct hydrates. He was inclined to think that the breaks might be due to change both in the complex water molecules and the sulphuric acid. He was inclined to believe that the hydrate, to which Mr. Lupton's conclusions related, did not begin to form in solution until the temperature sank to within a few degrees of its point of fusion. Dr. Morley said that a break in the curve should indicate that some new hydrate had just begun to form, but need not show what that hydrate was. Thus, a liquid of the composition $CaCl_2 8H_2O$ might be expected to contain, besides the hydrate $CaCl_2 8H_2O$, also higher and lower hydrates, such as $CaCl_2 9H_2O$ and $CaCl_2 7H_2O$. Prof. Rücker said that, in reality, Mr. Pickering's results were obtained, not by calculation, but by a method of observation and experiment applied to curves, which themselves represented the results of other experiments. It was admitted that the curves had to be specially drawn, and the scale of the co-ordinates carefully chosen, if the results were to be satisfactory, and probably the conclusions arrived at depended in a large measure on the details of this preliminary adjustment. In the case of the more striking changes in direction and curvature which were clearly visible in the original curve, the various differential curves did not add much to the information it supplied. He thought that the evidence afforded by these secondary curves of changes of curvature, not otherwise detected, was of the most untrustworthy character. Mr. Pickering said that Mr. Lupton's equation represented the rate of change of the densities as a straight line, while the figure which the actually observed rate of change formed was as different from a straight line as possible. The figures here referred to were the first differential figures (rate of change) deduced directly from the determinations themselves; the question of the accuracy attainable in differentiating a graph, raised by Prof. Ramsay, did not apply. He thought that Prof. Armstrong was somewhat rash in holding that a particular hydrate did not exist in solution at moderately high temperatures, because he had recognized it at low temperatures only, especially as he (the speaker) had been led to search for it, and finally to isolate it from results obtained at high temperatures. The multiplicity and complexity of the hydrates indicated must endanger the acceptance of his conclusions amongst chemists; and he was perfectly ready to accept any other explanation of the changes with weak solutions.—Ethylic *aa'*-dimethyl-*aa'*-diacetylpimelate and its decomposition-products, by Dr. F. S. Kipping, and J. E. Mackenzie. This paper contains an account of the preparation and properties of the following compounds: ethylic *aa'*-dimethyl-*aa'*-diacetylpimelate, *aa'*-dimethyl-*aa'*-diacetylpentane, *aa'*-dimethyl-*a*-acetylcaproic acid, *aa'*-dimethylpimelic acid, and ethylic-*aa'*-dimethylpimelate.—Volatile platinum compounds, by W. Pullinger. The author has studied the volatile compounds of platinum with chlorine and carbon monoxide described by Schützenberger. He describes their behaviour when heated in various gases; as they do not completely volatilize, a determination of the vapour-density was not possible. He describes a non-volatile compound of the formula $PtCl_6.C_2O_2$, and has also prepared the compound $PtBr_2CO$. Directions are given for the preparation of platinic bromide and iodide, from which it appears that spongy platinum readily dissolves in hot solutions of bromine in hydrobromic acid or of iodine in hydriodic acid.

Mineralogical Society, June 16.—R. H. Scott, F.R.S., President, in the chair.—The following papers were read:—On the occurrence of sapphire in Scotland, by Prof. M. Forster-Heddle.—On the optical properties of gyrolite, by Prof. M. Forster-Heddle.—On Fresnel's wave-surface, by L. Fletcher, F.R.S.

Linnean Society, June 18.—Prof. Stewart, President, in the chair.—Mr. W. H. Beeby exhibited specimens of *Hieracium protractum* and other plants collected in Shetland.—Mr. Stuart Samuel exhibited a dwarf specimen of *Acer palmatum*, and made some remarks on the dwarf trees artificially produced by the Japanese.—Mr. R. V. Sherring showed some cases of dried Bananas, and described a new method of preservation adopted in Jamaica to save waste of small parcels of fruit which would be otherwise unsaleable.—Mr. A. W. Bennett exhibited and made remarks upon a specimen of *Selaginella lepidophylla*, which was found to possess remarkable vitality, and upon proper treatment to resume its normal appearance after having been gathered some months.—Dr. R. A. Prior exhibited samples of the Spiked Star of Bethlehem (*Ornithogalum pyrenaicum*), and stated that, although described in British floras as a rare plant, it is so abundant on the hill pastures around Bath that it is brought to the market there in large quantities under the name of French asparagus, and sold for a penny a bunch.—Mr. R. A. Rolfe

Digitized by Google

showed two hybrid *Odontoglossums* with the parent plants—namely, *O. Wilckeanum* (produced from *O. crispum* and *O. luteopurpureum*) and *O. excellens* (produced from *O. pescatorei* and *O. triumphans*). These had first appeared as natural hybrids out of imported plants, and the parentage was subsequently ascertained under cultivation.—On behalf of Sir George Macpherson Grant, Mr. J. E. Harting exhibited some curiously abnormal horns of the Roe Deer (the result of disease), which had been taken from an animal found dead near Forres, N.B. For the purpose of comparison he exhibited some normal heads of the Roe from other parts of Scotland and Germany, and made some remarks on the causes of variation in the size and form of the antlers to which Roe Deer were peculiarly liable.—A paper was then read by Mr. Spencer Moore on the true nature of *Callus*, and in continuation of former remarks on the same subject (Linn. Soc. Journ., Bot., vol. xxvii., Nos. 187-188). He showed that the outer sieve-plates of the fig are obliterated by a substance giving all the dye reactions of *Callus*, which does not peptonize and will not yield proteid reactions. Many of the inner sieve-plates he found to be stopped up with a proteid *Callus* resembling in every way the substance of *Ballia* stoppers, and the proteid *Callus* of the vegetable marrow. It appeared that true *Callus* would dissolve in a solution of gum-arabic, but whether by agency of a ferment or of an acid he had not yet determined.—A second paper by Mr. Spencer Moore dealt with the alleged existence of protein in the walls of vegetable cells, and the microscopical detection of glucosides therein.

PARIS.

Academy of Sciences, June 22.—M. Duchartre in the chair.—Method for the determination of the equatorial co-ordinates of the centres of the plates which are to form the photographic map of the heavens, by M. Lœwy.—On a generalization of equations relating to the theory of the functions of a complex variable, by M. Émile Picard.—On the determination of the mechanical equivalent of heat, by M. Marcel Deprez. At the meeting of June 8, M. Miculesco described an apparatus he had employed for determining the mechanical equivalent of heat. It is now remarked that the same method was employed by Hirn in the experiments made by him in 1860, and in latter years by M. d'Arsonval.—On the formation of the leaves of *Æsculus* and of *Pavia*, and on the order of appearance of their first vessels, by M. A. Trécul.—On the apparent and real glycolytic fermentation in the blood, and on a rapid and exact method of estimation of glycogen in the blood, by MM. R. Lépine and Barral.—On a telephone receiver of reduced weight and dimensions, by M. E. Mercadier.—Observations of the new asteroid discovered at Nice Observatory on June 11, by M. Charlois. Observations for position were made on June 11 and 12.—Observations of the same asteroid made at Algiers Observatory with the telescope of 0·5 metre aperture, by MM. Rambaud and Sy. Observations for position were made on June 12 and 13.—Extraordinary luminous phenomena observed on the sun, by M. E. L. Trouvelot.—On the determination of spiral surfaces according to their linear element, by M. L. Raffy.—On certain systems of spherical co-ordinates, and on the corresponding triple orthogonal systems, by M. A. Petot.—On the damping of Hertz vibrations, by M. V. Bjerknes.—Transmission of light across disturbed media, by M. A. Hurion.—On the electrolysis of barium chloride, pure or mixed with sodium chloride, by M. C. Limb. With moderate currents the author fails to obtain metallic barium; with the pure salt an infusible body of high resistance is deposited; with the mixed salts chlorine is disengaged at the anode, and, from the results of analyses given, it would appear that among the products of the electrolysis some subchloride must be formed.—The calculation of the temperature of ebullition of any liquid whatever, under all pressures, by M. G. Hinrichs.—Action of heat on solutions of chromium salts: green salts of chromium, by M. A. Recoura.—The constitution of the green chromium salts is elucidated by means of the results of experiments following thermochemical methods.—Researches on osmium, osmiamic acid, and osmiamates, by M. A. Joly. Taking the revised atomic weight of osmium, the analyses of Fritzsche and Struve, as well as those of the author, point to $KNOsO_3$, and not to $K_2N_2Os_2O_5$, as the formula denoting the composition of potassium osmiamate. Relations may be traced between osmiamic acid and the nitroso-compounds of ruthenium, $RuNOCl_3$ and $RuNO(OH)_3$. $O=OsNO-OH$ may be viewed as the first anhydride of the hypothetical $OsNO(OH)_3$.—On the alkaline zirconates, by M. L. Ouvrard.—On the bromo-iodides of silicium, by M. A. Besson.—On the cyanogen compounds of magnesium, by M. Raoul Varet.—On the action of nitric acid of different degrees of concentration upon iron at various temperatures, by MM. Henry Gautier and Georges Charpy. The writers conclude from their experimental results that "*iron is always attacked by nitric acid, whatever its concentration.*" The action may proceed in two ways—(1) rapid, and accompanied by the disengagement of gas; (2) slow, and without evolution of gas. The latter corresponds to what is known as the passive state of iron.—Action of sodium benzylate upon camphocarbonic ether, by M. J. Minguin.—Comparative influences of the sulphates of iron and calcium on the preservation of nitrogen in naked soils and on nitrification, by M. P. Pichard.—On the value of animal *débris* as nitrogenous dressing, by MM. A. Muntz and A. C. Girard.—On the development of blastodermic leaves in Crustaceæ Isopodæ (*Porcellio scaber*), by M. Louis Roule.—On the disengagement of oxygen by plants at low temperatures, by M. H. Jumelle. It appears that in plants capable of resisting excessive humidity or cold the decomposition of carbon dioxide may continue at very low temperatures, even when respiration has ceased. Conifers such as the juniper-tree, and a lichen (*Evernia prunastri*), in light can assimilate the carbon in the air in an atmosphere having a temperature as low as $-30°$ or $-40°$ C.—The parasitic fungi of Acridians, by MM. J. Kunckel d'Herculais and C. Langlois.—On the supposed post-Secondary granites of Ariège, by M. A. Lacroix.—On the age of a porphyritic granite from the Western Pyrenees, by M. Joseph Roussel.—Experimental researches on muscular exertions, by M. Charles Henry.—Diseases of the bones of chimpanzees, gorillas, and orang-outangs, by M. Etienne Rollet.

Established nearly Half a Century
FOR
FOSSIL FISHES
AND
RECENT SHELLS.
Address to—
ROBERT F. DAMON,
WEYMOUTH.
Price Lists containing some *Thousands* of Species of *Recent Shells*, now Ready. Post Free, Twopence.

CONCHOLOGY.
New and Interesting Shells from New Guinea, Borneo, Philippine Islands, &c.
COLLECTIONS PURCHASED.
All kinds of Glass-Topped Boxes, &c., at Moderate Prices.
HUGH FULTON, Dealer in Recent Shells,
89 FULHAM ROAD, LONDON, S.W.

CEYLON, JAVA, BORNEO, AND NEW GUINEA INSECTS, especially Lepidoptera and Coleoptera, single or in lots. Also Orthoptera and Dragon flies. LAND AND FRESH-WATER SHELLS, offered at cheap prices.—H. FRUHSTORFER, Naturalist, care of German Consulate, Soerabaia, Java.

JAMES R. GREGORY,
Mineralogist and Geologist.
SPECIAL AND TYPICAL COLLECTIONS FOR STUDENTS, LECTURERS, MUSEUMS, &c. EVERY REQUISITE FOR PRACTICAL WORK. ROCK SPECIMENS, AND ROCK SECTIONS FOR MICROSCOPIC EXAMINATION. THE LARGEST STOCK AND GREATEST VARIETY IN LONDON. NEW LISTS NOW READY.
New Catalogue of Mineral Specimens,
Arranged for the Selection of Single Specimens, &c., with Prices. Also New Lists of Rare Minerals, Rock Specimens, Geological Apparatus, Collections, Hammers, and Microscopic Sections of Rocks.
And may be had post free on application at the Repository and Museum,
88 CHARLOTTE STREET, FITZROY SQUARE, LONDON.

F. H. BUTLER, M.A. Oxon., Assoc.R.S.Mines,
NATURAL HISTORY AGENCY,
158 BROMPTON ROAD, LONDON,
Dealer in Rocks, Minerals, Fossils, and other Objects of Scientific Interest.
Always in stock:—Micro-slips (crown and patent plate glass) and Micro-covers of all required sizes; Slide-boxes; Labels; Glass-topped Boxes; Card Trays; Hammers; Chisels; Collecting Bags and Hammer Straps; Cabinets; Blowpipe Apparatus; and low-priced Specimens of Rocks, Minerals, Fossils, Shells, and Birds' Eggs for selection. Collections to order. The new 12s. 6d. and 25s. Collections for agricultural students, farmers, land prospectors, and others, as supplied to the ROYAL AGRICULTURAL COLLEGE, CIRENCESTER, comprise carefully chosen series of typical rocks, rock-constituents, and minerals of economic importance. Recently received:—Ores of Iron, Nickel, and Cobalt, from Norway and Australia, and small specimens of Queensland Opal and cut New Zealand Jade.

MICRO-PETROLOGY.
Rock Sections for the Microscope, of special value and interest:—Porphyritic Basalt, Lion's Haunch, Edinburgh; Dolerite with Porphyritic Augite, Crawford John, Lanarkshire; Perlitic Pitchstone, Saxony; Pikrite, Inchcolm, Firth of Forth; Thulite, Norway; Siliceous Oolite, Pennsylvania; a Siliceous Rock with a perfect oolitic structure.
1s. 6d. each; extra large Sections, 1s. 9d. and 2s.
Collections of Minerals and Rocks for Prospectors and Students.
CATALOGUES POST FREE.

MESSRS. MACMILLAN AND CO.'S MATHEMATICAL WORKS.

GEOMETRICAL DRAWING.

Constructive Geometry of Plane Curves. By T. H. EAGLES, M.A., Instructor in Geometrical Drawing, and Lecturer in Architecture at the Royal Indian Engineering College, Cooper's Hill. Crown 8vo. 12s.

Elements of Descriptive Geometry. By J. B. MILLAR, Civil Engineer, Lecturer on Engineering in the Victoria University, Manchester. Second Edition. Crown 8vo. 6s.

Practical Plane and Descriptive Geometry. By E. C. PLANT. Globe 8vo. [*In preparation.*

Note-book on Practical Solid or Descriptive Geometry Containing Problems with help for Solutions. By J. H. EDGAR an G. S. PRITCHARD. Fourth Edition, Revised by A. MEZEZ. Glob 8vo. 4s. 6d.

A Geometrical Note-book. Containing Easy Problems i Geometrical Drawing preparatory to the Study of Geometry. For th Use of Schools. By F. E. KITCHENER, M.A., Head Master of th Newcastle-under-Lyme High School. 4to. 2s.

MENSURATION.

Elementary Mensuration. With Exercises on the Mensuration of Plane and Solid Figures. By F. H. STEVENS, M.A. Globe 8vo.

Elementary Mensuration for Schools. By S. TEBAY. Extra Fcap. 8vo. 3s. 6d.

Mensuration for Beginners. By ISAAC TODHUNTER F.R.S. 18mo. 2s. 6d. KEY. By Rev. FR. L. McCARTHY Crown 8vo. 7s. 6d.

TRIGONOMETRY.

An Elementary Treatise on Plane Trigonometry. With Examples. By R. D. BEASLEY, M.A. Ninth Edition, Revised and Enlarged. Crown 8vo. 3s. 6d.

Four-Figure Mathematical Tables. Comprising Logarithmic and Trigonometrical Tables, and Tables of Squares, Square Roots, and Reciprocals. By J. T. BOTTOMLEY, M.A., Lecturer in Natural Philosophy in the University of Glasgow. 8vo. 2s. 6d.

The Algebra of Co-Planar Vectors and Trigonometry. By R. B. HAYWARD, M.A., F.R.S., Assistant Master at Harrow. [*In preparation.*

A Treatise on Trigonometry. By W. E. JOHNSON, M.A., late Scholar and Assistant Mathematical Lecturer at King's College, Cambridge. Crown 8vo. 8s. 6d.

Elements of Trigonometry. By RAWDON LEVETT and CHARLES DAVISON, Assistant Masters at King Edward's School, Birmingham. [*In the press.*

Trigonometry of One Angle. Globe 8vo. 2s. 6d.

Examples for Practice in the Use of Seven-Figure LOGARITHMS. By JOSEPH WOLSTENHOLME, D Sc., late Professor of Mathematics in the Royal Indian Engineering College, Cooper's Hill. 8vo. 5s.

Trigonometry for Beginners, as far as the Solution of Triangles. By Rev. J. B. LOCK, M.A., Senior Fellow and Bursar of Gonville and Caius College, Cambridge. Third Edition. Globe 8vo. 2s. 6d. KEY. Crown 8vo. 6s. 6d.

Elementary Trigonometry. By the same Author. Sixt Edition (in this edition the chapter on Logarithms has been carefully r vised). Globe 8vo. 4s. 6d. KEY. Crown 8vo. 8s. 6d.

Higher Trigonometry. By the same Author. Fifth Ed tion. Globe 8vo. 4s. 6d. Both Parts complete in One Volume. Glo 8vo. 7s. 6d.

A Treatise on Spherical Trigonometry. With Applic tions to Spherical Geometry and Numerous Examples. By W. M'CLELLAND, M.A., Principal of the Incorporated Society's Scho Santry, Dublin; and T. PRESTON, M.A. Crown 8vo. 8s. 6d. Part I. To the End of Solution of Triangles, 4s. 6d. Part II., 5s.

Manual of Logarithms. By G. F. MATTHEWS, B.A. 8v 5s. net.

Text-book of Practical Logarithms and Trigonometr By J. H. PALMER, Head Master R.N., H.M.S. *Cambridge*. Dev port. Globe 8vo. 4s. 6d.

The Elements of Plane and Spherical Trigonometry By J. C. SNOWBALL, Fourteenth Edition. Crown 8vo. 7s. 6d.

Trigonometry for Beginners. By ISAAC TODHUNTER F.R.S. 18mo. 2s. 6d. KEY. Crown 8vo. 8s. 6d.

Plane Trigonometry. By the Same. Crown 8vo. 5 KEY. Crown 8vo. 10s. 6d.

[A New Edition, Revised by R. W. HOGG, M.A. *In the press.*

A Treatise on Spherical Trigonometry. By the Sam Crown 8vo. 4s. 6d.

ANALYTICAL GEOMETRY (Plane and Solid).

Exercises in Analytical Geometry. By J. M. DYER, M.A., Assistant Master at Eton. Illustrated. Crown 8vo. 4s. 6d.

An Elementary Treatise on Trilinear Co-ordinates, the Method of Reciprocal Polars, and the Theory of Projectors By the Rev. N. M. FERRERS, D D, F.R.S., Master of Gonville and Caius College, Cambridge. Fourth Edition, Revised. Crown 8vo. 6s. 6d.

An Elementary Treatise on Curve Tracing. By PERCIVAL FROST, D.Sc., F.R.S., Fellow and Mathematical Lecturer at King's College, Cambridge. 8vo. 12s

Solid Geometry. By the same Author. Third Edition. Demy 8vo. 16s.

Hints for the Solution of Problems in the Third Edition of SOLID GEOMETRY. By the same Author. 8vo. 8s. 6d.

Curve Tracing in Cartesian Co-ordinates. By W. WOOLSEY JOHNSON, Professor of Mathematics at the U.S. Naval Academy, Annapolis, Maryland. Crown 8vo. 4s. 6d.

The Geometry of the Circle. By W. J. M'CLELLAND, M.A.

An Elementary Treatise on Conic Sections and Alg BRAIC GEOMETRY. With Numerous Examples and Hints their Solution. By G. H. PUCKLE, M.A. Fifth Edition, Revis and Enlarged. Crown 8vo. 7s. 6d.

Conic Sections. By CHARLES SMITH, M.A., Master Sidney Sussex College, Cambridge. Seventh Edition. Crown 8vo. 7s. KEY. Crown 8vo. 10s. 6d.

An Elementary Treatise on Solid Geometry. Secon Edition. By the same Author. Crown 8vo. 9s. 6d.

Plane Co-ordinate Geometry, as Applied to the Straig Line and the Conic Sections. By ISAAC TODHUNTER, F.R. Crown 8vo. 7s. 6d.

KEY. By C. W. BOURNE, M.A., Head Master of King's College Scho Crown 8vo. 10s. 6d.

Examples of Analytical Geometry of Three Dime SIONS. By ISAAC TODHUNTER, F.R.S. New Edition, Revise Crown 8vo. 4s.

PROBLEMS AND QUESTIONS IN MATHEMATICS.

Army Preliminary Examination, 1882-1889, Speci- mens of Papers set at the. With Answers to the Mathematical Questions. Subjects: Arithmetic, Algebra, Euclid, Geometrical Drawing, Geography, French, English Dictation. Crown 8vo. 3s. 6d.

Cambridge Senate-House Problems and Riders, with SOLUTIONS:—

1875—PROBLEMS AND RIDERS. By A. G. GREENHILL, F.R.S. Crown 8vo. 8s. 6d.

1878—SOLUTIONS OF SENATE-HOUSE PROBLEMS By the Mathematical Moderators and Examiners. Edited by J. W. L. GLAISHER, F.R.S., Fellow of Trinity College, Cambridge. 12s.

A Collection of Elementary Test-Questions in Pure AND MIXED MATHEMATICS; with Answers and Appendices on Synthetic Division, and on the Solution of Numerical Equations by Horner's Method. By J. R. CHRISTIE, F.R.S. Crown 8vo. 8s. 6d.

Mathematical Papers. By W. K. CLIFFORD. Edited by R. TUCKER. With an Introduction by H. J. STEPHEN SMITH, M.A. 8vo. 30s.

Examples for Practice in the use of Seven-Figure LOGARITHMS. By JOSEPH WOLSTENHOLME. 8vo. 5s.

Weekly Problem Papers. With Notes intended for t use of Students preparing for Mathematical Scholarships, and Junior Members of the Universities who are reading for Mathemati Honours. By Rev. J. J. MILNE, Private Tutor. Pott 8vo. 4s. 6

Solutions to "Weekly Problem Papers." By the sam Author. Crown 8vo. 10s. 6d.

Companion to "Weekly Problem Papers." By t same Author. Crown 8vo. 10s. 6d.

Sandhurst Mathematical Papers for Admission into t Royal Military College, 1881-89. Edited by E. J. BROOKSMIT B.A., Instructor in Mathematics at the Royal Military Acade Woolwich. Crown 8vo. 3s. 6d.

Woolwich Mathematical Papers for Admission into t Royal Military Academy, Woolwich, 1882-88, inclusive. Edited E. J. BROOKSMITH, B.A. Crown 8vo 6s.

Mathematical Problems, on Subjects included in the Fi and Second Divisions of the Schedule of Subjects for the Cambrid Mathematical Tripos Examination. By JOSEPH WOLSTE HOLME, D Sc., late Professor of Mathematics in the Royal Indi Engineering College, Cooper's Hill. New Edition, greatly Enlarg 8vo. 16s.

MACMILLAN AND CO., LONDON. [2]

MACMILLAN & CO.'S NEW SCIENTIFIC BOOKS.

NEW VOLUMES OF MACMILLAN'S MANUALS FOR STUDENTS.

A NEW TEXT-BOOK OF CRYSTALLOGRAPHY.

Crown 8vo, Cloth, 6s.

ELEMENTS OF CRYSTALLOGRAPHY FOR STUDENTS OF CHEMISTRY, PHYSICS, AND MINERALOGY. By GEORGE HUNTINGDON WILLIAMS, Ph.D., Assistant Professor in the Johns Hopkins University. Crown 8vo.

*** A concise and elementary statement of the general principles of Crystallography, not intended as a complete treatise, but to furnish so much information on the subject as may be of service to students of other but allied branches.*

Crown 8vo, Cloth, 10s. 6d.

LESSONS IN ELEMENTARY BIOLOGY. By T. JEFFREY PARKER, B.Sc., F.R.S., Professor of Biology in the University of Otago, Dunedin, New Zealand. Illustrated.

NEW EDITION, REVISED.

Crown 8vo, Cloth, 10s. 6d.

A COURSE OF PRACTICAL INSTRUCTION IN BOTANY. By F. O. BOWER, D.Sc., F.R.S., Regius Professor of Botany, Glasgow.

NATURE:—"Everyone perusing the volume must be impressed with the high standard of its educational value. Teacher and student in this country are alike to be congratulated upon its publication. The former has now a thoroughly trustworthy laboratory guide to place in the hands of pupils, and the latter has a hand-book in his own language to which he can refer with confidence in his search after a sound knowledge of plant morphology. We conclude as we began by heartily welcoming the volume. We envy a student commencing to work with such a guide, and we are greatly mistaken if its effect is not very rapidly felt in the botanical teaching of the country."

ACADEMY:—"The work is one which should be in the hands of every practical botanist."

SATURDAY REVIEW:—"The types are good, easily obtained, and thoroughly worked out. . . . There is no padding, the text is to the point, and it assumes the presence of the plant concerned and the instruments in hand. We regard the absence of illustrations and of descriptive padding as important preventives of cram, and it should be clearly borne in mind that laboratory teaching suffers especially by the opening up of royal roads."

NEW VOLUME OF SIR WILLIAM THOMSON'S POPULAR LECTURES.

Crown 8vo, Cloth, 7s. 6d.

PAPERS ON NAVIGATION. By Sir WILLIAM THOMSON, LL.D., P.R.S., F.R.S.E., &c., Professor of Natural Philosophy in the University of Glasgow, and Fellow of St. Peter's College, Cambridge. [*Popular Lectures and Addresses*, Vol. III.

*** The papers on navigation treat of such subjects as pilotage, astronomical navigation, "dead reckoning" or "account," deep-sea surroundings. In the papers relating to the tides, besides the general facts, the subjects of gravitation, the influence of the Straits of Dover on the tides of the British Channel and the North Sea, the tides of the southern hemisphere and the Mediterranean, the sketch proposed plan of procedure in tidal observation, and analysis and the equilibrium theory of the tides, are discussed and dealt with.*

NEW EDITION OF VOL. I.

New and Revised Edition, Crown 8vo, Cloth, 7s. 6d.

THE CONSTITUTION OF MATTER. By Sir WILLIAM THOMSON, LL.D., P.R.S. With Illustrations. [*Popular Lectures and Addresses*, Vol. I.

NEW MATHEMATICAL SCHOOL BOOKS.

18mo, Cloth, 1s.

RIDER PAPERS ON EUCLID. BOOKS I. AND II. Graduated and Arranged in Order of Difficulty, with an Introduction on Teaching Euclid. By RUPERT DEAKIN, M.A., Balliol College, Oxford, Head Master of King Edward's School, Stourbridge.

BOOKS I. AND II. SEPARATELY.

18mo, 1s.

THE ELEMENTS OF EUCLID. BOOKS I. AND II. By I. TODHUNTER, F.R.S.

Globe 8vo, Cloth, 2s. 6d.

THE TRIGONOMETRY OF ONE ANGLE. By the Rev. J. B. LOCK, M.A., Author of "Arithmetic for Schools," "Trigonometry," "Elementary Statics," "Dynamics for Beginners," &c.

Globe 8vo, Cloth, 2s. 6d.

ELEMENTARY LESSONS IN SOUND, LIGHT, AND HEAT. By D. E. JONES, B.Sc., Professor of Physics in University College, Wales, Aberystwith, Author of "Examples in Physics," &c. With Illustrations.

*** It is hoped that this book will be found useful, not only in schools, but generally among candidates for the elementary stage of the Science and Art Department's Examination, or for London University Matriculation.*

Globe 8vo, Cloth, 2s. 6d.

THE PROGRESSIVE EUCLID. BOOKS I. AND II. With Notes, Exercises, and Deductions. Edited by A. T. RICHARDSON, M.A., Senior Mathematical Master at the Isle of Wight College; formerly Scholar of Hertford College, Oxford. Illustrated.

SCOTSMAN:—"A capital Euclid to begin on."

NATURE

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE.

"To the solid ground
Of Nature trusts the mind which builds for aye."—WORDSWORTH.

No. 1132, VOL. 44.] THURSDAY, JULY 9, 1891. [PRICE SIXPENCE.

Registered as a Newspaper at the General Post Office.]

[All Rights are Reserved.

THE NEW PATENT WATKIN ANEROID BAROMETER.

Amongst many unsolicited Testimonials the following has been received by the maker:—

EDINBURGH, May 31, 1889.

DEAR SIR,—I have just returned from a six weeks' stay at the Ben Nevis Observatory, and while there had an opportunity of testing the admirable qualities of your new "Watkin" Aneroid. The result has been most satisfactory, the extreme error noted being only about $\frac{1}{100}$ of an inch. During my stay at the Observatory the Aneroid was frequently tested by taking it down 2000 feet and then comparing it with the standard on my return. The results obtained speak volumes for the high class workmanship and great accuracy you have attained in the manufacture of this instrument.

(Signed) R. C. MOSSMAN, F.R.M.S., Observer, Scott. Met. Soc.

To be obtained of all Opticians and Wholesale Houses.

J. J. HICKS, 8, 9, & 10 HATTON GARDEN, LONDON.

"The 'STAR' MICROSCOPE is a modern marvel at its low price. The lenses alone are worth the money."—*British Medical Journal.*

BECK'S

£2 2s. to £5 5s.

NEW MODEL "STAR" MICROSCOPE

It is made throughout in brass, neatly japanned, and is not only first-rate in optical qualities, but is now a handsome, well-finished instrument.

R. & J. BECK, 68 Cornhill, London, E.C.

BROWNING'S BINOCULARS.

THE "ECONOMICAL" FIELD-GLASS.

This Binocular has achromatic object-glasses 1¼ inch in diameter, and sliding shades to shelter the object-glasses from sun or rain, and is fitted in a solid leather sling case, price £1 5s.; sent free

Illustrated Catalogue of Binoculars post free.

CITY AND GUILDS OF LONDON INSTITUTE.

PRESIDENT: H.R.H. THE PRINCE OF WALES, K.G.

CHAIRMAN OF COUNCIL: THE RIGHT HON. THE EARL OF SELBORNE, F.R.S.

SESSION 1891-92.

The Matriculation or Entrance Examination for the CENTRAL INSTITUTION will be held on SEPTEMBER 21-24 and for the Day Department of the TECHNICAL COLLEGE, FINSBURY, on SEPTEMBER 29.

CENTRAL INSTITUTION.

The Courses of Technical Instruction at the Central Institution of the City and Guilds of London Institute are adapted to the requirements of persons who are preparing to become Civil, Mechanical, or Electrical Engineers, Chemical and other Manufacturers and Teachers.

MATHEMATICAL DEPARTMENT, under the direction of Prof. HENRICI, F.R.S. ENGINEERING DEPARTMENT, under Prof. UNWIN, F.R.S., M.I.C.E. (Dean of the Institution). PHYSICAL AND ELECTRICAL DEPARTMENT, under Prof. AYRTON, F.R.S. CHEMICAL DEPARTMENT, under Prof. ARMSTRONG, Ph.D., F.R.S.

The NEW SESSION COMMENCES on SEPTEMBER 30. The Entrance Examination will be held on SEPTEMBER 21-24.

Programme and full Particulars of Courses of Instruction, and of the Entrance Scholarships, on application at the Central Institution, Exhibition Road, or at the Office of the City and Guilds Institute, Gresham College, E.C.

TECHNICAL COLLEGE, FINSBURY.

The DAY CLASSES at the City and Guilds Technical College, Finsbury, provide Technical Instruction for Mechanical and Electrical Engineers and Technical Chemists, and are under the direction of Prof. S. P. THOMPSON, D.Sc., F.R.S. Principal of the College, Prof. J. PERRY, F.R.S., and Prof. R. MELDOLA, F.R.S.

The NEXT SESSION commences on OCTOBER 6. The Entrance Examination will be held on SEPTEMBER 29.

For further Particulars of Day and Evening Classes, Scholarships, &c., apply at the College, Leonard Street, City Road, E.C., or at the Office of the City and Guilds Institute.

JOHN WATNEY, Hon. Secretary.

City and Guilds of London Institute, Gresham College, E.C.

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR.

AGRICULTURAL DEPARTMENT.

An ASSISTANT LECTURER in AGRICULTURE will be appointed in SEPTEMBER next, for one year, at a Salary of £120.

Applications must be sent in on or before SATURDAY, SEPTEMBER 5, to the undersigned, from whom information as to conditions of Appointment and Duties may be obtained.

W. CADWALADR DAVIES, Secretary and Registrar.

University College of North Wales, Bangor,
July 1, 1891.

TWO ENTRANCE SCHOLARSHIPS in

NATURAL SCIENCE, of the value of 125 Guineas (*i.e. a Free Admission*) and £60, are awarded annually in OCTOBER at ST. THOMAS'S HOSPITAL MEDICAL SCHOOL, London, S.E.

For Particulars, apply to Mr. G. RENDLE, Medical Secretary.

E. NETTLESHIP, Dean.
G. H. MAKINS, Vice-Dean.

UNIVERSITY OF GLASGOW.

THE JOHN ELDER CHAIR OF NAVAL ARCHITECTURE (INCLUDING MARINE ENGINEERING).

Owing to the death of the late Occupant, the Chair is now Vacant. Candidates intending to apply for the Vacancy are invited to lodge with the Secretary of the University Court, Mr. ALAN E. CLAPPERTON, 91 West Regent Street, Glasgow, 20 Printed Copies of their Applications and any Relative Testimonials on or before JULY 31 Next.

THE AGRICULTURAL COLLEGE, ASPATRIA.

PRINCIPAL—DR. H. J. WEBB, B.Sc.

Thorough practical and scientific Training in Agriculture. Preparation for the Colonies. Students gained the First, Third, and Fourth Scholarships of the Royal Agricultural Society, 1888; First in Agriculture Junior Scholarships, 1889; First in Agriculture Senior Scholarships, 1890.

NOTICE OF REMOVAL

FROM

BIRMINGHAM TO MALVERN

Of THOMAS BOLTON'S Agency for the Supply of Specimens of "Pond-life" for the Microscope.

NEW ADDRESS—

T. E. BOLTON, FARLEY ROAD, MALVERN LINK.

Volvox globator, Closterium lunula, Brachionus rubens, Plumatella repens and other beautiful living objects now available. Amœba, Protococcus Vorticella, Hydra, &c., for use in the study of Biology.

Specimen Tube, One Shilling, Post Free.

SERIES OF 26 TUBES FOR 21s.

List Free.

MARINE BIOLOGICAL ASSOCIATION.

NOTICE.

Only Three Tables now remain unoccupied. Investigators desiring to carry on work during the present Summer are therefore requested to make Early Application.

Sales by Auction.

TUESDAY, JULY 14.

NATURAL HISTORY SPECIMENS.

MR. J. C. STEVENS will sell by Auction at his Great Rooms, 38 King Street, Covent Garden, on TUESDAY, JULY 14, at half-past 12 precisely, Natural History Specimens, comprising Valuable Collections of British and Foreign Lepidoptera and Coleoptera, including many Rarities, Butterflies received direct; Minerals, Fossils, Shells, a fine Collection of Heads and Horns of Animals, well Mounted, Bird and Animal Skins, Birds set up in Cases, Birds' Eggs, Entomological and other Books, Good Cabinets, &c.

On view the Day prior, 10 till 5, and Morning of Sale, and Catalogues had.

A FIRST-CLASS MICROSCOPE, with Fittings by BECK; 400 Slides by best Makers; and an 8½-inch Reflecting Telescope, Mirror by WITH; all the property of a Private Gentleman, and in good condition, will be offered for Sale by Auction by Mr. J. C. STEVENS, at his Great Rooms, 38 King Street, Covent Garden, on FRIDAY NEXT, JULY 17.

STANLEY

Mathematical Instrument Manufacturer to H.M. Government, Council of India, Science and Art Department, Admiralty, &c.

Mathematical, Drawing, and Surveying Instruments of every description,

Of the Highest Quality and Finish, at the most Moderate Prices.

Illustrated Price List Post Free.

W. F. S. obtained the only Medal in the Great Exhibition of 1862 for Excellence of Construction of Mathematical Instruments, and the only GOLD MEDAL in the International Inventions Exhibition 1885 for Mathematical Work. Silver Medal, Architects' Exhibition, 1886.

THE VERTEBRATE FAUNA OF SCOTLAND.

Fourth Volume.

A VERTEBRATE FAUNA of the ORKNEY ISLANDS. By T. E. BUCKLEY, B.A., F.Z.S., and J. A. HARVIE-BROWN, F.R.S.E., F.Z.S. One Volume. Small 4to. Illustrated with Photogravure Plates from Drawings by J. G. MILLAIS, as well as from Photographs taken specially for the Book. Price 30s.
[*Now Ready.*

Third Volume.

THE BIRDS OF IONA AND MULL, and other Natural History Notes, 1852-70. By the late HENRY DAVENPORT GRAHAM, and Edited by J. A. HARVIE-BROWN, F.Z.S., &c. Illustrated from the Authors' Sketch-books. One Volume. Small 4to. Price 21s. net.

"There is a freshness and originality about them which makes them extremely pleasant reading."—*Field.*

"In the seclusion of the 'sacred island,' even now invaded by the tourist for only a brief season, Graham had not merely ample opportunities for studying natural history, but also leisure for thinking. Consequently, the book is full of original suggestions, derivations of words, scraps of folk-ore, &c."—*Athenæum.*

"If Captain Marryat, instead of devoting his time after leaving the service to writing novels, had wandered off to a desolate island and turned wild-fowler and ornithologist, he might well have written such a book as that which the literary executors of the late H. D. Graham have issued under the sober title of 'The Birds of Iona and Mull.'"—*Spectator.*

Second Volume.

A VERTEBRATE FAUNA of the OUTER HEBRIDES. By J. A. HARVIE-BROWN, F.R.S.E., and T. E. BUCKLEY, F.Z.S. One Volume. Small 4to, with Maps and Plates. Only a very few Copies remaining at 63s. net.

"It is rarely, indeed, that a book comes before us which promises so little and gives so much as the delightful volume which Messrs. Harvie-Brown and Buckley have dedicated to the Outer Hebrides."—*Saturday Review.*

Edinburgh: DAVID DOUGLAS, 10 Castle Street.

ZOOLOGICAL SOCIETY'S LATEST PUBLICATIONS.

Proceedings of the General Meetings for Scientific Business of the Zoological Society of London for the year 1891, Part I., containing the Papers read in January and February, with Fourteen Plates. Price 12s.

Transactions of the Society, Vol. XIII., Part 2. Price 21s., containing the following papers:—

Prof. W. K. Parker, F.R.S., on the Morphology of a Reptilian Bird (*Opisthocomus cristatus*), with Four Plates.

Prof. F. Jeffrey Bell, F.Z.S., Contributions to our Knowledge of the Antipatharian Corals, with Two Plates.

These Publications may be obtained at the Society's Office (3 Hanover Square, W.), at Messrs. LONGMANS, the Society's Publishers (Paternoster Row, E.C.), or through any bookseller.

THURSDAY, JULY 9, 1891.

THE UNITED STATES ENTOMOLOGICAL COMMISSION.

Fifth Report of the United States Entomological Commission on Insects Injurious to Forest and Shade Trees. By Alpheus S. Packard, M.D., Ph.D.

VERY valuable Reports have been presented by the United States Entomological Commission from time to time. Among these may be mentioned that upon "The Rocky Mountain Locust," prepared by Prof. Riley in 1878, which is a most exhaustive record of the habits of this terrible pest, and of methods of prevention and remedies against its attacks. Later on, an equally valuable and instructive Report was submitted with regard to the cotton worm (*Aletia argillacea*), very destructive to the cotton plant, whose crop it has reduced in some seasons from 30 to 75 per cent. in the principal cotton-producing States. Both these elaborate works, as might be expected from their authors, Prof. Riley and Dr. Packard, who practically constituted this Entomological Commission, are full of interesting experiments, ingenious contrivances, and subtle devices, to circumvent the insect hordes advancing with the insistance of invading armies.

This Report upon "Insects Injurious to Forest and Shade Trees" is perhaps not so exciting or painfully interesting, as the harm caused to trees is not so directly felt as that occasioned to various food crops and other crops of the field by locusts and caterpillars innumerable, and the name of the insects described therein is legion, and their individual mischief is comparatively small.

As Dr. Packard says, "a volume could be written on the insects living on any single kind of tree, and hereafter it may be expected that the insect population of the oak, elm, poplar, pine, and other trees will be treated of monographically." Kaltenbach, in "Die Pflanzenfeinde, aus der Klasse der Insekten," gives accounts of 537 European species of insects injurious to the oak, 107 to the elm, and 396 to the willow. Perris, a French observer, has recorded no less than 100 species of insects found upon the maritime pine.

The attacks of insects upon forest trees and upon shade trees, or trees planted for shade and ornamentation in parks, streets, and other public places, are becoming far more numerous and serious, just as in the case of all cultivated crops under the sun. In the United States these attacks are creating intense interest, as the forests are of the highest commercial importance, and have been extensively decreased by clearing, by wanton and accidental fires, and other causes. This Report, then, is opportune, and must be of great service, as it demonstrates the sources of the injuries, and suggests means of preventing them or of diminishing them.

The French, German, Austrian, and Italian Departments of Agriculture are giving much attention to this subject, for it is found that the forest trees of these countries are becoming more liable to harm from insects. In Great Britain some kinds of trees, notably of the pine tribe, have suffered much damage from insects hitherto unknown, or, at least, not reckoned as injurious. There are, without doubt, many others unsuspected in British woods and forests, slowly but surely working great mischief.

Dr. Packard shows that trees are attacked in every part and in every conceivable manner by insects. Their roots, leaves, bark, fruit, and twigs are all more or less subject to their visitations. The most curious of those which affect the roots is the "seventeen year" Cicada, whose larvæ remain for over sixteen years attached to the rootlets of the oak, other forest trees, and fruit trees, as the pear and apple. According to Prof. Riley, these larvæ are found at a great depth, sometimes as much as 10 feet below the surface. The female, resembling a locust, deposits long slender eggs in an unbroken line upon the terminal twigs of oak and other trees in May and June. Sometimes the twigs are so "badly stung" by this oviposition that the trees are seriously injured. The length of wood perforated on each branch sometimes varies from one to two and a half feet, averaging probably eighteen inches, and appearing to be the work of one female. From the eggs the larvæ hatch out in six weeks and drop to the ground, in which they live, sucking the roots of the trees for nearly seventeen years, the pupa state lasting but a few days.

A formidable enemy of the "live-oak" (*Quercus virens*) is an enormous beetle, *Mallodon melanopus*, Linn., whose larva, three inches long and an inch in thickness, bores into the roots upon which it lives. As a result of the work of this insect in South Georgia and Florida, "vast tracts, which might otherwise have become forests, enriching the ground with annual deposits of leaves, are reduced to comparatively barren scrub, in which the scattered oak-bushes barely suffice to cover the surface of the sand." The eggs are laid by the beetle in the foot, or collar, of the tree, just below the surface of the ground. It is not known how long the larvæ live, but their life must extend over several years, "since the roots occupied by them grow to a large size, while they show an abnormal development, and become a tangle of vegetable knots. In fact, the entire root in its growth accommodates itself to the requirements of the borer within." The effect on the tree is to kill the original stem, which becomes replaced by a cluster of insignificant and straggling suckers, forming, perhaps, a clump of brushwood.

Among the tree-borers, other than beetles, the oak "carpenter worm," the caterpillar of *Prionoxystus robiniæ*, Peck, is the largest and most destructive. It is larger and far more abundant than the European caterpillar of *Cossus ligniperda*, or goat-moth, belonging to the same family of Cossidæ, but it sinks its tunnels deep in towards the heart of the tree, not confining its mischief to the limbs and large branches like the goat-moth caterpillar. Fitch says of this:—"Of all the wood-boring insects in our land, this is by far the most pernicious, wounding the trees most cruelly. The stateliest oaks in our forests are ruined, probably in every instance where one of these borers obtains a lodgment in their trunks." Another species of Cossus, known as *Cossus centerensis*, bores into poplars. Its appearance and habits also resemble those of the goat-moth, well known in this country.

There are numbers of boring beetles, of the families Buprestidæ, Cerambycidæ, and Scolytidæ, whose larvæ

Digitized by Google

make burrows, passages, and galleries in trees, mainly just under the bark. Of these, the elm-tree borer, *Saperda tridentata*, is prominent, often killing elm-trees by wholesale, both in forests and in public parks. The larvæ bore in the inner bark, making irregular furrows and tunnels upon the surface of the wood, which "is, as it were, tattooed with sinuous grooves, and the tree completely girdled by them in some places." In the State of Illinois attention was attracted to the gradual decay and death of white elms (*Ulmus americanus*) in rows in some towns. The leaves fell off in the summer, and some of the branches died. Finally, the tree perished altogether. On peeling off the bark, half-grown larvæ of *Saperda tridentata* appeared in considerable numbers, and the manner in which the bark had been mined by the Saperdas gave sufficient evidence of the cause of the death of the tree. Prof. Forbes, State Entomologist of Illinois, says: "From the present appearance of the elms throughout the towns of Central Illinois, it seems extremely likely that this pest will totally exterminate this tree, unless it be promptly arrested by general action." It is recommended that all affected trees should be removed and destroyed in autumn and winter, before the beetles have a chance to emerge from the trunks. This beetle is not quite an inch long; its larva is rather more than an inch in length, having a large flat head.

Fir trees, especially the white pine (*Pinus strobus*), the yellow pine (*Pinus mitis*), and *Pinus rigida*, are much injured by the pine borer or "sawyer," *Monohammus confusor*. "I have seen," writes Dr. Packard, "hundreds, perhaps nearly a thousand, dead firs, whose trunks were riddled with the holes of these borers." Dr. Packard cites a correspondent of the *North-Western Lumberman* who reported that "extensive and valuable forests of yellow pine in the Southern States are destroyed by a worm commonly called here a 'sawyer,' or flat head." White pine trees are also much beset by the "wood engraver" bark beetle (*Xyleborus xylographus*, Fitch), so called because it makes beautifully regular and artistic furrows on the surface of the wood under the bark. It is the most common, and probably the most pernicious, of all the insects that infest the forests of white pine in New York State, and of yellow pine in the States south of New York.

A weevil, the white pine weevil (*Pissodes strobi*), frequently spoils the finest white pines in parts of America by placing numerous eggs in the bark of the topmost shoots of fir trees; the larvæ from these make mines in the wood and pith, causing the shoots to wither and die, thereby occasioning a fork, or crook, at this point. This is a very small insect, not three-quarters of an inch long, and the larvæ are not half an inch in length.

There is a mighty army of caterpillars of various moths described in this Report, which devour the foliage of trees of all kinds in American forests and gardens. Several species of Clisiocampa and Gasteropacha, of the Bombycidæ, assail oak, willows, ash, chestnut, apple, and pear trees. These are termed "tent" caterpillars, as they live in webs of a tent-like form, as the *Clisiocampa Neustria*, or lackey moth, in Europe. But the most voracious of caterpillars are the "fall web worms" of the moth *Hyphantria cunea*, Drury. For instance, in 1886, the city of Washington, as well as its vicinity, was entirely overrun by them. All vegetation, except that not agreeable to their tastes, suffered greatly. Fine rows of shade trees, which grace the streets and avenues, were leafless in midsummer, and covered with hairy worms. The pavements were strewn with moultings of the caterpillars and their webs, which were blown about unpleasantly by the wind.

Because they are hairy they have comparatively few enemies, among birds at all events. The "English sparrow," fast becoming as great a nuisance in the United States as the rabbit in Australasia, will not look at them, and has driven away by its pugnacity many birds that would eat them. Fortunately there are insect enemies which prey upon them, as the *Mantis carolina*, or "rear horse," an extraordinary insect of the same family as the "praying" mantis, and the "wheel bug" (*Prionidus cristatus*). Several parasitic insects also greatly check the spread of this moth. One fly, *Telenomus bifidus*, Riley, lays its egg within the tiny egg of the moth, in which all the transformations of the fly take place, and its food and lodging are found. In due time, having cleared out the egg, the fly emerges.

Mr. Bates, in his graphic account of tropical insects, has pictured many that are made to closely resemble their surroundings, for their preservation and other purposes. In his well-known paper on mimicry, he alludes to the insects known as Phasmidæ, or "spectre" insects, as especially typical of this adaptation to circumstances, preserved and augmented, as Darwin says, "through ordinary selection for the sake of protection." Mr. Wallace brings forward the Phasmidæ as striking instances of mimicry, remarking that "it is often the females alone that so strikingly resemble leaves, while the males show only a rude approximation."

Species of this family of Phasmidæ are mischievous to trees in America, principally the oak and the hickory. The chief of these is the *Diapheromera femorata*, Say., popularly called "walking-stick," "walking-leaves," "stick-bug," "spectre," "prairie alligator," "devil's horse." This insect, especially the female, is so like the twigs of trees in colour and appearance, that it is difficult to discover it. It has a habit, too, of stretching out the front legs and feelers, greatly enhancing this resemblance. While the vegetation is green the "walking-sticks" are green; when the foliage changes in the autumn they also change colour; and when the trees are bare of leaves they closely resemble the twigs on which they rest. The eggs are dropped upon the ground from whatever height the females may be, "and, during the latter part of autumn, where the insects are common, one hears a constant pattering, not unlike drops of rain, that results from the abundant dropping of these eggs, which in places lie so thick among and under the dead leaves that they may be scraped up in great quantities." Prof. Riley adds, with regard to these singular creatures and their wonderful resemblance to the oak vegetation upon which they occur, "one cannot help noticing still further resemblances. They are born with the bursting of the buds in the spring; they drop their eggs as the trees drop their seeds, and they commence to fall and perish with the leaves, the later ones persisting, like the last leaves, till the frost cuts them off."

There is not space enough to do more than allude to the sawflies, another class of insects fearfully injurious to trees of divers kinds. Many of these Hymenoptera, as in Great Britain and other European countries, mainly of the genus *Nematus*, clear off the leaves of forest and fruit trees. Others attack firs, notably some species of Lophyrus and Lyda, as the *Lophyrus abietis*, *Lophyrus pinetum*, and *Lophyrus pini-rigidæ*, and some of the Lyda. Cameron, in his monograph of the British phytophagous Hymenoptera, states that there are fifteen species of Lophyrus in North America, and that the species of Lyda are common there.

Lophyrus abietis and *Lophyrus abbotii* appear to do the same harm in America to firs as the *Lophyrus pini* in Scottish fir plantations, whose larvæ not only eat the leaves but the bark of the young shoots, frequently occasioning great losses.

An instructive account is given in this work of the effect of temperature upon insects. It is the fashion in Great Britain to say that insects are killed by hard frosts. But they are not killed in countries—as America, for example—whose winters are far more severe. Dr. Packard, quoting Judeich and Naitsche's "Lehrbuch der Mittel-Europäischen Forstinsektenkunde," observes that "the influence of even very great cold on the normal hybernating stages of our insects is not very great. In the summer of 1854 the 'nun' moth had very generally laid its eggs in Eastern Prussia uncovered on the bark, and these did not freeze in the hard winter of 1854–55. According to the observations of Regener, openly exposed caterpillars of the pine silk-worm endured 10° F. The pupa froze at 21° F., the moth at 19° F. According to Duclaux, the eggs of the silk-worm endure well, remaining two months in a temperature of 17° F. Great fluctuations of temperature during the winter produce an abnormal interruption of the winter's rest or hibernation, and thus cause the death of many insects." It will be noticed that in all these cases the insects were unprotected, whereas there is generally some kind of protection during the winter for insects in all stages, provided by their instinct.

Not the least useful part of the Report is that treating of remedies for insect attacks, and machines and engines for applying them. Arsenical poisons, known as Paris Green and London Purple, are strongly recommended for spraying or syringing trees infested with the larvæ of beetles and sawflies, or the caterpillars of moths. These have been recently introduced into England, being advocated by the Board of Agriculture, but have not been extensively adopted yet, owing to the natural prejudice against the use of poisons. In America they are employed most extensively and with the greatest benefit. By means of these the potato beetle (*Doryphora decemlineata*) was circumvented, and the cotton and boll worms checked, and the onslaughts of many other insects materially lessened. For Aphides, Scale insects, and other insects which suck the sap of leaves, "emulsions" or washes of soft soap, or "jelly soaps," made directly from fish oil and concentrated lye, or whale-oil soap, are prescribed. Also kerosine, naphtha, and petroleum, applied in a fine spray, or mixed with soap and soap jelly, forming "emulsions." These remedies act by contact, being applied principally to insects which do not eat the leaves, as well as by making the surroundings unpleasant and unbearable. Powdered substances, as pyrethrum, hellebore, and sulphur, are not much employed for forest work, but cases frequently arise warranting their use in a limited way. Hellebore, as gooseberry growers in Kent and Cambridgeshire well know, is of especial value against all sawfly larvæ. Sulphur is valuable against the red spider (*Tetranychus telarius*), and is used alone or in connection with emulsions of kerosene.

Numerous machines are in vogue for putting on washes and powders, from the small "knapsack" machine carried on the back, to huge tanks on wheels, fitted with powerful hand-pumps and long lengths of hose, through which liquids are forced to great heights; for very high trees, tall ladders are used, which are set near the trees, upon which men mount, and direct the hose into the topmost branches. For smaller trees and shrubs, a barrel fixed on wheels, having a good force-pump with hose, is adopted. Pumps are also fitted into tanks of all shapes and sizes, and moved from place to place by hand or horse-power. To distribute the liquids there are endless nozzles or jets contrived with much ingenuity to send forth fine mists, or sprays, or continuous volumes. It will suffice to say that the best of these is the cyclone, or Riley nozzle, which is just being introduced into Great Britain.

Foresters, and all concerned in the management of woods and forests, public parks, and gardens, would do well to consult this work for information as to the various insect enemies of trees, and the best means of dealing with them. It is quite impossible in a review to give anything more than a general idea of its scope and nature.

PHYSICAL RELIGION.

Physical Religion. The Gifford Lectures delivered before the University of Glasgow in 1890. By F. Max Müller. (London: Longmans, 1891.)

THE present volume, which embodies the author's second course of Gifford Lectures, with notes and appendices, is devoted to the consideration of "Physical Religion," that is the religion which finds its object the Infinite in or behind the phenomena of Nature. The author's previous writings have made it clear that for the simplest and most abundant manifestation of this form of religion we must go to the Veda, so his first task in the lectures before us is to tell once more the familiar story of the discovery, the character, and the age of the Veda. To this survey four lectures are devoted, and, in conclusion, the author—not without duly considering all that in recent years has been urged to the contrary—reaffirms his conviction that the hymns of the Rig Veda cannot have been collected later than 1000 B.C.

In the sixth lecture the author deals with the evolution of the idea of God. It is often supposed—even by philosophers of repute—to be a sufficient account of the earliest form of religion to say that men worshipped stones and other fetishes as their gods. But, as the professor well remarks—

"Does it never strike these theorizers that the whole secret of the origin of religion lies in that predicate, *their gods?* Where did the human mind find that concept and that name? That is the problem which has to be solved; everything else is mere child's play."

Digitized by Google

And he exhibits the process by which Agni (the Vedic god of fire), from being originally nothing but "the mover," came to be called *deva;* and it is this word *deva* which when examined yields the clue to the development, and teaches us a lesson of the highest importance :—

"Guided by language we can see as clearly as possible how, in the case of *deva*, the idea of God grew out of the idea of light, of active light, of an awakening, shining, illuminating, and warming light. We are apt to despise the decayed seed when the majestic oak stands before our eyes, and it may cause a certain dismay in the hearts of some philosophers that the voice of God should first have spoken to man from out the fire. Still, as there is no break between *deva*, bright, as applied to Agni, the fire, and many other powers of nature, and the *Deus optimus maximus* of the Romans—nay, as the God whom the Greeks ignorantly worshipped was the same God whom St. Paul declared unto them—we must learn the lesson, and a most valuable lesson it will turn out to be, that the idea of God is the result of an unbroken historical evolution, call it a development, an unveiling, or a purification, but not of a sudden revelation."

The two following lectures are devoted to the detailed following out of the biography of Agni, who appears in a variety of characters as the sun, the fire on the hearth, lightning, the messenger between gods and men, and priest. Finally, divested of his material character altogether, he is raised to a sublimer level as creator, ruler, and judge. The value of this inquiry, into the details of which we have no space to enter, lies in the fact that it involves the refutation of two objections which are frequently urged—with or without knowledge—against natural religion by the professors of so-called supernatural religion. The first is that natural religion, though it may lead men to a conception of "gods," is powerless to suggest to them the conception of God. This is directly contradicted by the history of Agni, whom we can watch, as it were, passing through many stages of growth until he becomes in the end "a supreme god, *the* Supreme God, till his very name is thrown away, or is recognized as but one out of many names by which ancient seers in their helpless language called that which is, the One and All." Driven from this position, however, the orthodox objector usually takes up another, and contends that the supreme God of natural religion lacks some if not all of the lofty attributes which he is enabled to know and to predicate of his own God by supernatural revelation. But Prof. Max Müller's answer to this objection is equally decided :—

"Trusting to the fragments that have been preserved to us in the Veda, to the remains of the most childish as well as the most exalted thoughts, we may say that natural religion, or the natural faculties of man under the dominion of the natural impressions of the world around us, can lead, nay, has led man step by step to the highest conception of deity, a conception that can hardly be surpassed by any of those well-known definitions of deity which so-called supernatural religions have hitherto claimed as their exclusive property."

In the ninth lecture the Professor leaves for a while the field of his special studies to glance at the history of religious ideas among other peoples than the Âryas of the Veda. And it is noteworthy that he fully recognizes the possibility that Jehovah himself may originally have been a god of fire. But we must protest against the way in which he alludes to Abraham, the legendary founder of Hebrew monotheism, as if his historical character had never been questioned. It is, of course, perfectly open to any one to believe that Abraham was a real individual, who received a "revelation," whatever that word may be defined to mean (see p. 221) ; but at the same time, in a course of lectures addressed to an academic audience, it should surely have been mentioned that this is an hypothesis, which Renan, for instance, among Semitic scholars, does not even take the trouble to discuss.

In the lecture on the mythological development of Agni, we would call attention to the importance assigned to *riddles* as a cause of the growth and preservation of mythology. To take a simple example :—

"After the Âryas in India had once arrived at the conception that fire was apt to consume the fire-sticks, or that Agni had eaten his father and mother, they seem to have amused themselves by asking such questions as, Who eats his own parents? The answers given would then enter upon many details, more or less far fetched, and the question would continue to be asked between young and old people."

And we think that this is a far more natural explanation of the origin and popularity of such stories than the hypothesis, which has no external evidence to support it, that the Âryas were simply ascribing to Agni the atrocities which they practised themselves.

Finally we come to the question, What can a study of natural religion teach us? "Why," answers Prof. Max Müller, "it teaches us that religion is natural, is real, is inevitable, is universal," and he proceeds to exhibit in detail one or two of the more important implications of this great lesson. With regard to miracles, for instance :—

"Is it not clear that in the eyes of those who believe in the omnipresence of the Moral Governor of the world, miracles, in the ordinary sense of the word, have become impossible, and that to them either every event is miraculous or no event can claim that name. Before the great miracle of the manifestation of God in nature, all other miracles vanish. There is but one eternal miracle, the revelation of the Infinite in the finite."

The Professor then shows by a series of examples that the tendency to ascribe a miraculous birth to the founders of religions is natural and widespread, and asks by what right people claim a different character for the legends of the birth of Jesus than for the similar legends told of Buddha and Mohammed. The honesty and candour with which the question is stated are specially welcome at the present time, when it is becoming the fashion with ecclesiastical amateurs in Biblical criticism to blow hot and cold, as it were, with the same infallible mouth—that is, to reject the miracles of the Old Testament, but retain those of the New. For instance, in a recent manifesto, highly recommended as providing a temporary shelter for the destitution of the semi-reasonable, there is, on the one hand, some tall talk about the imaginative performances of "a dramatizing Jew" in the Old Testament, while, on the other hand, we are gravely informed that "the Church can insist upon the truth" of all that is recorded in the New Testament. That this cheap substitute for criticism will eventually be discredited, even in England, we have no doubt whatever. Meanwhile we cordially recommend

Digitized by Google

the present volume not only for the interest of its subject-matter, but as an example of the masterly application of the only method which in these inquiries can lead to sure results.

THE KARWENDEL ALPS.

Das Karwendelgebirge. Von A. Rothpletz. Separat-Abdruck aus der *Zeitschrift des Deutschen und Oesterreichischen Alpenvereins.* With Map. (München, 1888.)

THE Karwendel Alps are a mountain mass lying to the north of the valley of the Inn, between Innsbruck and Jenbach, and bounded on the east by the Achensee, on the north and west by the upper valley of the Isar, and on the south roughly by a line drawn along the Hinterauthal (the highest part of the valley of that river) to Schwaz, in the Innthal. This region has been explored and mapped by Herr Rothpletz, with the assistance of other workers, and it is described as consisting of three roughly parallel ranges. Though their peaks do not attain to a very great elevation, the higher summits ranging from 6500 feet to rather over 8200 feet, their grand cliffs of cream-coloured limestone and their pine-clad slopes afford very beautiful scenery.

In this part of the Alps the mountain masses are wholly composed of sedimentary deposits which range from the Trias to the Neocomian. The oldest are the *Werfener Schichten*, a mass of sandy shales and sandstones, often containing numerous flakes of biotite, indicative, in all probability, of the denudation of the crystalline masses which form the floor of the Mesozoic rocks in the Alpine region. They correspond in age roughly with the upper part of the Bunter in Germany and England. Then comes the remainder of the Trias, including the Muschelkalk, followed by the representatives of the Rhætic, the Lias, and other Jurassic deposits, and a part of the Neocomian, a marine series from top to bottom. Neither the last nor the Jurassic system attains to a great thickness, but both the Rhætic and the Trias are represented by great masses of rock. In the one, the *Haupt-dolomit* occasionally attains to a thickness of 500 metres; in the other, one member, the *Myophorienschichten*, is said to be equally important. Careful descriptions of each subdivision, with lists of the more characteristic fossils, are given in the memoir. Neither Cretaceous nor Tertiary strata occur to bridge over the interval between the Neocomian and the superficial Glacial or post-Glacial deposits.

The physical history of these ranges is made the subject of an elaborate discussion. Herr Rothpletz is of opinion that, at some epoch after the Neocomian and before the commencement of the folding process by which the existing Alpine ranges were upraised, the region was affected by movements which produced a system of faults. In consequence of these, a zone of upheaval was bordered on either side by one of depression. These caused important modifications in the great east and west folds, to which the Eastern Alps are due; the rocks in the two troughs were crushed together; the upheaved tracts were upthrust. A folding plate represents an ideal section of the region after the "pre-Alpine" movements, side by side with one which shows its present state.

There can be no doubt that, in explaining the physical structure of the Alps, we have to take account of much more than the later Tertiary foldings to which the formation of the mountain-chain is due, such as the old irregularities of the pre-Mesozoic land-surface; and any important system of faults could not fail to produce very marked effects. Also, it seems indubitable that there were interruptions to the downward movement in parts of the Alpine area during the later Mesozoic and the earlier Tertiary times, which may, very probably, have caused faults such as are described by Herr Rothpletz. These, it may be noticed, appear to run obliquely to the general trend of the main folds.

Herr Rothpletz, in conclusion, expresses an opinion adverse to those geologists who consider that glaciers have played an important part in the erosion of valleys, and calls especial attention to the Soiernsee, a small lake lying in a fold of the *Plattenkalk*, which, in his opinion, indicates that "the movement of flexure acted in this case with greater rapidity than the erosive action of streams or glacier."

The geological map is on a scale of 1 : 50,000; the separate memoir, of octavo size, contains 76 pages, with 9 plates and 29 smaller illustrations. It also includes a full list of works bearing on the district. So far as we can judge, it is an elaborate and valuable contribution to the knowledge of a region but little known to English travellers, who, however, occasionally pass very near to it along the margin of the beautiful Achensee.

T. G. B.

OUR BOOK SHELF.

Graphical Statics. Two Treatises on the Graphical Calculus and Reciprocal Figures in Graphical Statics. By Luigi Cremona. Translated by Thomas Hudson Beare, Professor of Engineering and Applied Mechanics, Heriot-Watt College, Edinburgh. (Oxford: Clarendon Press, 1890.)

TREATISES on this and allied subjects of the Graphical Calculus are not uncommon in our language; but, although nowadays indispensable for engineering purposes, the subject does not flourish in our theoretical courses of instruction.

The theorems of Graphics once stated—that is, drawn out carefully on the drawing-board—are obvious, or at least do not lend themselves to verbal written demonstration, so that for purposes of competitive examination, the controlling influence of modern education, the subject of Graphical Statics and Calculation is useless.

Geometrical drawing is not taught in our public schools and Universities; and the student in a technical college only requires the bare minimum of Graphics, sufficient to enable him to pass on to practical developments; so that we fear the elegant abstract theorems on the use of signs in Geometry, as applied to lines and areas, graphical multiplication, division, involution and evolution, solution of equations, centroids, rectification and graphical analysis generally, will receive but slight attention.

There is a note of defiance in the Author's Preface to the English edition of "Reciprocal Figures in Graphical Statics" (the second treatise): "At a time when it was the general opinion that problems in engineering could be solved by mathematical analysis only, Culmann's genius suddenly created Graphical Statics, and revealed how many applications graphical methods and the theories of modern (projective) geometry possessed," &c.

The preface to "Geometry of Position," by R. H. Graham, must be consulted for the counterblast in favour of Maxwell's claim to the honour of priority.

A. G. G.

The History of Commerce in Europe. By H. de B. Gibbins. With Maps. (London: Macmillan and Co., 1891.)

THE chief defect of this little book is that the author does not bring into sufficient prominence the geographical element in commercial history. What are the geographical conditions which have favoured the growth of particular industries in special localities? And in what ways have such conditions affected the interchange of commodities between one part of the world and another? Mr. Gibbins has not, of course, neglected these questions, but he scarcely seems to have realized that they are of vital importance for the scientific presentation of his subject. On the other hand, his appreciation of the action of historical causes in the development of commerce is excellent; and for a general view of commercial progress his manual will be of much service to students. After an introductory chapter he considers "ancient commerce," by which he means the commerce of the Phœnicians, the Carthaginians, and the Greek colonies. He then deals with the ancient Greek States and Rome as trading communities. Next comes "mediæval commerce," in connection with which he has much that is interesting to say about the Italian cities, the Hansa towns, mediæval trade routes and fairs, the manufacturing centres of Europe, and other topics. Under "modern commerce" he treats of the commercial empires in the East, the commercial empires in the West, English commerce from the sixteenth to the eighteenth century, European commerce in the seventeenth and eighteenth centuries, the industrial revolution in England and the Continental wars (1793), modern English commerce, and the development of commerce in France, Germany, Holland, Russia, and the other European States. The maps are very good, and add considerably to the value of the text. We may also note that the volume includes a useful series of questions on the various chapters, and two appendices, in one of which there is a list of British produce and manufactures in 1840 and 1889, while the other consists of a table showing the present colonial empires of European Powers.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Albert University.

THE remarks of Mr. Thiselton Dyer upon the draft charter of the "Albert University" have my fullest concurrence. I have never desired to see such a University as is sketched in that charter set up in London by the side of the existing University. The charter and the general scheme of its proposals never obtained the sanction of the professoriate of University College whilst I was a member of that body; and many of us were as active as circumstances allowed us to be, in opposing its federal principles and bureaucratic tendency. That University and King's Colleges should be united in some way to form a University is one proposition: that the University should take the particular form excogitated by Sir George Young is another. It is well that it should be generally known that the elaborate (and to my mind mischievous) constitution sketched in the draft charter of the Albert University is the product of the devotion and ingenuity of Sir George Young, an active member of the Council of University College.

I was not aware, when I wrote in NATURE some weeks ago on this subject, that the Lord President of the Privy Council had determined to set aside the recommendations of the late Royal Commission, and to hurry through a formal inquiry into the draft charter propounded by the Councils of University and King's Colleges.

So long as the matter was in the hands of the Commission, this charter, put forward by the Councils of the two Colleges, was merely one of many suggestions as to the proper form which a new or reconstituted University of London should take. It was notorious that the Councils' support of Sir George Young's scheme did not represent the attitude either of the Professors of the two Colleges or of those throughout the country who have special knowledge of Universities and of the best methods of academical organization.

The Royal Commission of 1888 was appointed to inquire "whether any and what kind of new University or powers is or are required for the advancement of higher education in London." The Commission took a large amount of evidence from interested parties—practically none from persons outside the London institutions concerned—and recommended that the University of London should be invited to meet the needs set forth in such documents as the draft charter of the Albert University, by some modifications of its constitution and procedure. In the event of a failure on the part of the University to do this, the Commissioners recommended *that the matter should be referred back to them.*

My support of the claim of University and King's Colleges to be incorporated as some kind of University has always depended on the assumption that no Commission or other serious authority could possibly accede blindly, and without full consultation of the best authorities in the land, to the scheme embodied in the Albert University draft charter. The Commissioners took, it seems to me, the only rational view of that charter—namely, that it might serve as a suggestion to the University in Burlington Gardens for a reform which would meet, at any rate, some of the objections raised to the existing constitution of the latter body.

Lord Cranbrook, however, seems anxious to hurry on the shelving if not the solution of the University of London question. Instead of referring the matter back to the Commissioners, he takes the matter out of their hands. The Commissioners have *never reported in answer to the question set before them.* No one knows whether they think any, and, if so, what kind of new University is required in London.

Having failed to settle the question for the time being by such a reform of the University in Burlington Gardens as Mr. Dyer advocates, the Commissioners ought—according to their own recommendation—to have been allowed to proceed further. "It is now ascertained," they would have said, "that the existing University of London will not reform itself in the way we have suggested: what sort of University shall we now recommend, if any?" They might have suggested the coercion of the Convocation of Burlington Gardens by an Act of Parliament; or they might have—after inquiring from authorities in Oxford, Cambridge, Dublin, Edinburgh, and wherever else some understanding of the nature and objects of Universities happens by chance to dwell—recommended the formation of a professorial University in London similar to those of Scotland and of Germany.

I confess that it has always been my hope, though not my expectation, that they would take the latter course. I am sure that if they had proceeded to take the evidence of experts in University matters, and had not attached undue importance to the proposals of competing corporations, they would have found the balance of unprejudiced opinion to be in favour of a "professorial" rather than a "federal" University. The difficulty they would have had to contend with would have been that some of their own body, and nearly every witness whom they lately examined, are very far from having a clear idea as to what are the possible forms of University organization, what the merits and the demerits respectively of the "federal" and the "professorial" scheme as now in practice in Europe. This is obvious enough from the printed "Minutes of Evidence taken before the Royal Commissioners appointed to &c.," which can be purchased of Messrs. Eyre and Spottiswoode for about half-a-crown.

But whatever else the late Royal Commission might have done, I cannot believe that they would have proposed to set up so extraordinary and useless a piece of complicated machinery as the Albert University (of the draft charter) by the side of Burlington Gardens. The draft charter, having failed to reform the existing University of London, ought, one would have thought, to have been torn up.

Digitized by Google

I quite agree with Mr. Dyer that it is little short of monstrous for the Government to set up in London *two* such organizations as Burlington Gardens and the federal Albert; there is the strongest reason for insisting that there shall be only one of them, whether Convocation likes it or not.

Meanwhile, we are no nearer than we were seven years ago to the formation in London of a Senatus Academicus which shall retain in the metropolis—in contact with its statesmen, lawyers, physicians, authors, and the intelligent men and women of wealth and leisure—the strongest and best of our scholars, historians, physicists, and biologists. Is it well that the President of the Royal Society of London should have to travel from Glasgow to the meetings of that body? that its senior Secretary should spend his life in Cambridge? and that there is absolutely no professorship in the metropolitan area which can, by virtue of its dignity or its pecuniary value, entice men from the seclusion of provincial Universities? The draft charter of the Albert University does not even attempt to supply such a want. It actually makes the London professor more a creature of competition and the servant of red-tape officialism than he is at this moment.

E. RAY LANKESTER.

MR. THISELTON DYER has done good service in pointing out the nature of the proposed Albert University, which, unfortunately, seems not unlikely to be the result of the discussions that have been going on for the last six or eight years with respect to a "Teaching University for London." Should the charter petitioned for by the Councils of University and King's Colleges be granted, it will not constitute a teaching University in any real sense, but, as Mr. Thiselton Dyer says, an institution very similar to what the present University of London was as constituted by the original charter of 1837. There are, of course, differences of organization and machinery, such as the institution of Assemblies of Faculties and Boards of Studies (which the existing University might institute next week, if it saw fit), but there is little or nothing that can be looked upon as a difference of principle. The nearest approach to this are the provisions: (1) that the Colleges whose students are to be eligible as candidates for degrees shall have a certain amount of representation on the governing body of the University; (2) that the claim of additional Colleges to enter the University shall be decided by the governing body of the University, subject to appeal to the Queen in Council (instead of, as in the charter of 1837, being decided on directly by the Crown); (3) that "the University may appoint lecturers independently of a College or medical school to give instruction in any subject, whether it be or be not included in a Faculty."

With the exception of this last provision, slipped in at the end of Section V., "*University Degrees and Certificates*," as though modestly shunning the notice that a separate heading might call to it, there is no allusion from beginning to end of the draft charter to any teaching to be done by or through the University as such. If it comes into existence, it will be a mere examining University over again. Such a scheme can go no appreciable way towards remedying the existing defects of University organization in London. It is not easy to see what public advantages are likely to result from it. Seeing that it is put forward as representing the views of University College, London, it does not seem irrelevant to the present stage of the discussion to say that the scheme of the Albert University has never been submitted to a general meeting of the Governors of the College.

University College, London. G. CAREY FOSTER.

The Draper Catalogue.

ON p. 133 of the current volume of NATURE (June 11) Mr. Espin gives a comparison of the Draper Catalogue of Stellar Spectra with the catalogues of Vogel and Dunér. Vol. xxvi. of the *Harvard Annals*, of which the first part will be distributed in a few days, discusses at length the deviations from Vogel and also from the similar catalogue of Konkoly. A second examination was made on photographic plates having a long exposure of those stars which appeared discordant. Since spectra of the first type pass by insensible degrees into the second, and these in turn into the third, no two observers would agree on the exact points of distinction. Moreover, different characteristics would distinguish the photographic and visual portions of the spectra (*H. C. Annals*, xxvi. pp. 177, 189). Some discrepancies, as in the case of the three fourth-type stars which are erroneously entered in the Draper Catalogue, are due to errors of identification (xxvi. p. 192). The photographic spectra of faint third-type stars are always indistinguishable from those of the second type (xxvi. p. 178). See also remarks following Table II. of vol. xxvii. The bright lines cited by Mr. Espin are probably portions of the spectra contained between dark bands or lines (xxvii. p. 3). Spectra are difficult to classify when measured as faint as 6·5; not when the final magnitude is brighter than 6·5, as might be inferred from Mr. Espin's reference (xxvii., preface).

The Cuckoo.

I DO not know if the hibernating of swallows and other summer visitors is still a debated question or not, but the following account of a cuckoo may be of interest to some of your readers.

In the month of August a young cuckoo was taken from its nest and kept in the house, where it lived and throve—until one day in November, when it escaped and could not be found. But in the following March, during the usual spring cleaning, this very bird was discovered on a shelf in the back kitchen, hidden away behind some old pots and pans, still alive, and asleep, with all its feathers off, and clothed only in down, the feathers lying in a heap round the body. The rude awakening which the cuckoo received was fatal to its existence, for it survived only for a few hours.

Colour-Associations with Numerals, &c.

THE following record of experiments extending over a period of nearly ten years, under exceptionally good conditions, appears to me to be worthy of attention. A preliminary note on the subject was printed in *Science*, vol. vi. No. 137, 1885, p. 242, part of which is reproduced below.

In 1880, while I was in Washington, I read Mr. F. Galton's note on "Visualized Numerals," in NATURE, vol. xxi. p. 252.

After I came to Wisconsin—probably late in 1881, or early in 1882—I mentioned my own entire inability to visualize numerals or anything else of the kind to a member of the University faculty, Prof. Owen. I was interested to learn that, when a boy, he had always conceived the vowel sounds as having colour, and that he still retained some traces of this early habit.

I spoke of this subject in my house shortly after; and my daughter Mildred, then about seven years old, said she also had colours for the days of the week, as follows: Monday, *blue*; Tuesday, *pink*; Wednesday, *brown* or *grey*; Thursday, *brown* or *grey*; Friday, *white*; Saturday, *pure white*; Sunday, *black*. It was said laughingly, and at the time it passed to my mind as a joke—that she wished in sport to assume the idiosyncrasies of elder persons. A few days after, I questioned her on these colours, and she gave the same replies. It was again spoken of as a kind of a joke and a question of memory, but I wrote the colours down in my memorandum-book for 1882. A year later I produced this, and again questioned her—this time seriously—and found her answers the same as at first. Again, on August 5, 1885, her replies were the same. The tenacity of a child's memory is very remarkable; but I was convinced this was not a case of memory and imagination, but a true phenomenon of the kind referred to. I therefore went farther, and asked her if there were any other phenomena of the same sort (she was now ten and a half years old). I found that each of the letters of the alphabet had a colour to her, as follows:—

A, *white*; B, *blue*; C, *yellow, cream colour*; D, *dark blue*; E, *red*; F, *black*; G, *green*; H, *white*; I, *black*; J, *grey, brown*; K, *grey*; L, *dark blue*; M, N, *brown*, not much colour; O, *yellow*; P, *green*; Q (?); R, *brown*; S, *yellow*; T, *green*; U, *yellow*; V, *white*; W, *brown*; X, Y, not much colour; Z, *greenish*.

The prevalence of yellow and green, and the scarcity of reds and pinks, are noteworthy. I found that she knew these colours instantly, and when I asked for them in any order. What is more remarkable, she could instantly name the brown letters in a group, the black ones, &c. Apparently she did not require to pass the alphabet in review to decide this. The numbers also had colours to her, as follows:—

1, *black*; 2, *cream colour*; 3, *light blue*; 4, *brown*; 5, *white*; 6, *crimson, pink*; 7, *greenish*; 8, *white*; 9, *greenish* (?); 10, *brown*; 11, *black*; 12, *cream colour*; 13, *blue*; 14, *brown*; 15, *white*; that is, 11 had the same colour as 1, 12 as 2, 13 as 3, &c.

These colours were also named instantly, and in any order, and in groups.

[1] If anything.

Note.—The column for June 1891 was sent to me in a letter, as written in the table, except that *Wednesday* and *Thursday* are described as "brownish-grey, with little dots," and *Friday* as "white, with dots." The letter says:—"Is this right? I write this out without giving much thought to it—writing as fast as I can write. I am not quite definite in my mind as to the colours of 9, 10, G, T, K, O, Q, S, V; but the others have never changed. The days of the week I *never* think of without thinking of their corresponding colours. They have always remained the same. I don't quite remember if I have ever told you about the dots before, but they have always been there, and are like minute pencil marks showing through the colour. *Tuesday* is slightly dotted."

The table gives the results of the earlier experiments together with others which have been subsequently obtained. The later experiments have been made under circumstances which are peculiarly favourable—usually by correspondence during my daughter's absence at school.

The table undoubtedly represents vivid and permanent associations of colour with numerals, letters, &c. If we collect the various signs which correspond to a given colour, it appears, on the whole and in a general way, that the colour is associated with the *sound* rather than with the *form* of a letter. For example, G, P, T, Z are *green*; A, H, eight, are *white*; V, Friday, five, are *white*; C, S, Saturday, are yellow, &c. There are numerous exceptions to this, however, and it is by no means proved that there is a real law here. I simply make the suggestion on account of its bearing on the question whether or no we can think without words. It is clear that many experiments, such as are exhibited in the table, must be made before the time will arrive for definite conclusions to be drawn. Perhaps this brief note may induce others to print the results of similar investigations.

Mount Hamilton, June.

Erratic Barometric Depression of May 23-29, and Hailstorm of May 24.

IN connection with the very interesting letter of the Rev. Clement Ley (on p. 150), descriptive of the barometric depression which passed over these isles towards the end of last month, the following extract from a letter of mine published in the local press, with a view of obtaining further information, but without success, may be of interest. At the time when the centre of the depression lay over the mouth of the Thames, as mentioned by Mr. Ley, this neighbourhood was being visited by a thunderstorm of great severity and lengthy duration, and at 6 p.m. the rain gave place to hail, and "In the short space of twenty minutes the ground and roofs of houses were covered with a compact layer of frozen rain-drops, which at the end of half an hour (6.30 p.m.), when the storm had abated and given place again to rain, I found to have an average depth of 0·75 inch, though the stones were then reduced to about half their original size. . . . But few of the hailstones, which were nearly all ovarious in form, were smaller than 0·375 by 0·250 inch, and three which I picked up at random at 6.10 p.m. when the storm was at its

Digitized by Google

height, measured respectively 0·065 by 0·051 inch, 0·437 by 0·562 inch, and a spherical one had a diameter of 0·5 inch." Such large hailstones are, I believe, rarely met with in storms near London. This one seems to have been confined to a comparatively small area, the hail falling in its greatest severity at Leyton, and not extending much beyond Walthamstow, Stratford, West Ham, and here. B. J. HOPKINS.

Forest Gate, E., June 22.

"An Alphabet of Motions."

I HAVE lately found the following extract in Arthur Young's "Travels in France, in 1787," which I fancy is not generally known. It occurs in Betham Edwards's late edition (Bell and Sons), at p. 96.

"In the evening to Mons. Lomond. . . . In electricity he has made a remarkable discovery. You write two or three words on a paper; he takes it with him into a room and turns a machine inclosed in a cylindrical case, at the top of which is an electrometer, a small fine pith ball; a wire connects with a similar cylinder and electrometer in a distant apartment; and his wife, by remarking the corresponding motions of the ball, writes down the words they indicate, from which it appears he has formed an alphabet of motions. As the length of the wire makes no difference in the effect, a correspondence might be carried on at any distance."

Stewart House, Wrotham Road, Gravesend, June 24.

On a Cycle in Weather Changes.

IT is known that Prof. Brueckner, of Berne, in a work on "Klimaschwankungen," published a short time ago, offers a large amount of evidence for the view that our globe is subject to a weather-cycle of about 35 years, a series of cold and wet years, or warm and dry ones, recurring at about that interval. Has it been noticed in this connection that Bacon, in one of his essays (No. lviii. "Of Vicissitude of Things"), makes reference to such a cycle? The passage is as follows:—"There is a toy which I have heard, and I would not have it given over, but waited upon a little. They say it is observed in the Low Countries (I know not in what part) that every five-and-thirty years the same kind and suit of weathers comes again; as great frosts, great wet, great droughts, warm winters, summers with little heat, and the like, and they call it the *prime*. It is a thing I do the rather mention, because, computing backwards, I have found the same concurrence." A. B. M.

THE FORECAST OF THE INDIAN MONSOON RAINS.

AFTER an interval of twelve more or less prosperous years, following on the memorable Madras famine of 1876-77, and the drought and fearful mortality of North-Western India in 1877-78, India seems once more to have entered on one of those prolonged series of adverse seasons which put a severe strain on the protective powers of its Government, and, despite all human precaution, bring suffering, disease, and premature death to thousands of its industrious peasants, and to even larger numbers of the impoverished outcasts who form the lowest fringe of its teeming population, fighting the precarious battle of their life at all times on the verge of destitution. The drought in Ganjam in the autumn of 1889 has been followed by the failure of the late autumnal rains over the central districts of the Carnatic towards the close of last year, and the too familiar machinery of relief works for the able-bodied, and doles of food to the helpless indigent, has been in active operation for several months past in the districts around Madras. Another monsoon, another season of those periodical rains on which depends the fate of millions, is now due and overdue, and there comes from India an ominous note of warning that there is reason to fear that more than one great province of the empire, or certain portions of them, may again this year lie parched and barren, their young crops withering and shrivelled under the dry west wind, while, month after month, men scan with ever-growing anxiety the pale dust-obscured sky and scattered ball-shaped clouds that never mass themselves to rain-clouds, but mock their hopes with the promise of showers that never fall to moisten the sun-baked soil.

And this warning, alas! is no mere guesswork of credulous and speculative minds, such as in these latitudes certain of our would-be weather prophets love to put forth at hazard, to furnish the topic of a day's gossip to the million, or haply to win for themselves a summer day's reputation with the uninstructed, in the event of a successful issue. Certainty, indeed, there is not and cannot be till science shall have extended its domain far beyond its present limits; but, in India, the stately march of the seasons is but little obstructed by the vicissitudes of fugitive cyclones and anticyclones, that originate we know not how, and disappear by some concurrence of causes equally beyond our ken. In the tropics, and in the realm of the monsoons, all weather phenomena are more massive and slower in progress, and each great change of seasons is heralded by signs which, if we can as yet but vaguely interpret them, are at least recognizable as such, and, with a certain allowance for possible error, must be accepted as timely monitors of what is likely to follow. These it is that, whether rightly or wrongly deciphered, furnish the basis for the present warning. To those who, like the present writer, have followed for many months past, not without anxious interest, the telegraphic and other reports periodically transmitted from India, it comes as no surprise, but as a confirmation of misgivings long entertained though only now backed by the warranty of full official evidence. The events of the next three months may yet belie the present indications, and that they may do so is still our fervent hope; but it would be folly to ignore them, and to shut our eyes to the probabilities that they seem to portend.

For the last eight years it has been one of the duties of the Indian Meteorological Department, some time early in June, to prepare, for the information of Government and the public, a forecast of the probable character of the summer monsoon, based on the reports of the snowfall on the Himalaya and the western mountains, and on the indications afforded by the weather of the previous winter and spring. The possibility of framing such a forecast was in a measure foreseen by the Famine Commissioners appointed by the Home Government after the disastrous famines of 1876 and 1877, of which Commission General R. Strachey, the true founder of the Meteorological Department of India, was the scientific member; and it is in no small degree due to the weighty advocacy of this Commission that the Department owes its present extension and importance. Mr. Eliot's forecast for the coming season is now before us. It sets forth at length the general and special grounds on which he bases his conclusions; and these, though duly guarded by the reminder of their essentially empirical character, and of the unavoidable imperfection of our information regarding certain important data, are expressed in terms that leave unhappily no doubt of the adverse character of the outlook.

Attention was first directed to the apparent connection of the Himalayan snowfall with the prevalence of dry land winds in India, in the year 1877, and about the same time the late Prof. S. A. Hill and Mr. Douglas Archibald showed that, as a general rule, an unusual cold weather rainfall in Northern India was followed by a deficient rainfall in the ensuing summer monsoon. In a paper published in the Proceedings of the Royal Society in 1884, these two classes of facts were shown to be merely different phases of the same phenomenon, and a summary was given of all the evidence on the subject that had been accumulated up to that date. Since then, there has been but one year of heavy Himalayan snowfall, viz. 1885,

Digitized by Google

and in that year the rains were greatly delayed on the Bombay coast, and were very deficient in North-Western India in June, July, and September, commencing late, and terminating early. During the past winter and spring the snowfall on the North-Western Himalaya and the mountains of Afghanistan and Baluchistan has been excessive—indeed, as Mr. Eliot states, unprecedented during the last twenty-five years—and from the reports received from the civil officers and observatories in the mountain districts, he estimates that an average fall of 40 feet, if not considerably more, must have fallen over all the higher ranges, from Murree eastward to Garhwal, if not to Central Nepal. That it was the same on the less accessible range of the Hindu Kush we have reason to believe from the casual reports that were received during the last winter, and we know that in Southern Europe and even in Northern Africa, snow fell down to the sea-level, and was such as has hardly been experienced certainly during the greater part of the present century. The phenomenon has therefore been one of widespread incidence, and indicates some remarkable and rare condition of those higher strata of the atmosphere which, we have now reason to believe, are the seat of the more important changes that regulate the vicissitudes of the weather of the globe.

Concurrently with this exceptional extension of the snowfall to low latitudes of the temperate zone, the Indian registers afford evidence of certain abnormal features, which are such as have been noticed on former occasions of unusual snowfall on the North-West Himalaya, and the bearing of which on the weakness of the summer monsoon is more clearly traceable. In fact, they tend to link the two phenomena together, whether we regard them as the common effects of some more remote agency, or as displaying the different steps of a physical sequence of cause and effect. The most important of these are: the unusual rainfall over the whole of Northern India in the past winter and spring, amounting to from two to three times the average in the Punjab, where it was heaviest; a prevailing low temperature in Northern and especially North-Western India, together with a corresponding excess of temperature in Assam, Burma, and Southern India; and finally, a persistent excess of atmospheric pressure in the former region and a deficiency in the latter. These anomalous features have characterized more or less all the months of the present year, especially March and May. As estimated by European standards, the anomalies of this last element may indeed appear small. For instance, the mean excess at Peshawar in May was 0·052 inch, at Mooltan 0·041, and at Quetta 0·049 inch, while the deficiency at Calicut was 0·040 inch, and at Sibsagar 0·031 inch. Taken together, they constitute an anomalous gradient from north-west to south and east of something under a tenth of a barometric inch in distances of 1300 and 1500 miles. But in India such differences are relatively large, and, as former experience has abundantly shown, very significant. As temporary phenomena they might indeed be of little importance; but, lasting as they have done through nearly half a year, they point to an anomalous state of the atmosphere which is evidently persistent, and is distinctly adverse to the northern incursion of the summer monsoon. Taking the general mean of all parts of the empire, the atmospheric pressure has been above the average in every month of the present year. With respect to the winds, Mr. Eliot remarks:—"South-easterly winds have been unusually prevalent in Bengal and Behar during the months of April and May, and north-westerly and northerly winds on the west coast of India as far south as Cochin. The unusual prevalence of north-westerly winds on the Bombay coast in the month of May was one of the features of the weather in 1876, 1883, and 1885, in which years the monsoon was greatly retarded on that coast."

Finally, after reviewing the chief characteristics of other years in which the Himalayan snowfall has been heavier than usual, Mr. Eliot draws the following conclusions with respect to the probable character of the monsoon rains of the present year in the different provinces of India:—

"(1) Snowfall conditions on the Western Himalayas, &c., and the pressure conditions in India are very unfavourable to the establishment of a strong and early monsoon on the Bombay coast. It is very probable that it will not be established in full strength on the Bombay coast before the third or fourth week in June, and it is probable that it will be below its average strength, and may be withdrawn from Upper India earlier than usual in September.

"(2) The snowfall conditions in the Eastern Himalayas, and the pressure conditions in North-Eastern India and Burma, are favourable to the advance of a moderately strong or strong monsoon in the Bay of Bengal earlier than usual, and to its establishment in Burma and Bengal before or about its normal period," and Burma, Bengal, and Assam are expected to receive an average or more than an average rainfall; Behar and the eastern districts of the North-West Provinces about the usual amount. In Southern India it is thought probable that the rains may be retarded, but that Malabar and Southern India generally are likely to receive favourable rain during the monsoon.

On the other hand, it is pointed out that "conditions are very unfavourable for Rajputana, and also to some extent in Guzerat, the southern districts of the Punjab, and the western districts of the North-West Provinces. It is probable the rainfall will be more or less deficient over the whole of that area, and possible that the deficiency may be large and serious." In Northern Bombay and Berar it is thought that "the rainfall is more likely to be slightly deficient than up to its normal amount," and that in the Central Provinces it will be "fairly normal."

From this abstract it will be seen that the region in which drought is chiefly to be anticipated is the western provinces of Northern India, comprising Rajputana, Guzerat, the southern districts of the Punjab, and the western districts of the North-West Provinces; provinces the average rainfall of which does not exceed between 20 and 30 inches, and which time after time have been the seat of disastrous famines. Now there is one consideration relevant to this subject of which no mention is made in Mr. Eliot's report, and which, notwithstanding that its bearing is purely empirical, cannot, we think, be entirely disregarded when dealing with the question of probabilities. This is the fact, first pointed out by the Famine Commissioners, that between 1782 and 1877, on no less than five occasions, a drought in Southern India was followed by a drought in Northern or rather North-Western India in the succeeding year. It does not seem possible, in the present state of our knowledge, even to suggest any physical explanation of this remarkable sequence, but it has been repeated too often to allow of our regarding it as purely fortuitous, and unfortunately it only tends to strengthen the probability of the adverse conditions inferred by Mr. Eliot from the existing state of things.

It must be confessed, then, that, according to our present means of judgment, the present outlook is by no means hopeful. The mere fact of a retardation of the monsoon rains would not in itself afford cause for serious anxiety. According to the latest report from Madras, indeed, this part of Mr. Eliot's forecast seems to have been justified by the event, for on June 26 the Governor of Madras telegraphs that the south-west monsoon rains have not set in properly in the interior, and are very light even on the Malabar coast,[1] whereas the date at which they are

[1] We have taken the liberty of altering the punctuation of this telegram to bring it into accordance with sense and fact.

Digitized by Google

usually expected is the end of May or the beginning of June. The really critical months in North-Western India are August and September. If the rainfall is then abundant and continuous up to the end of the third week in September, with a final shower or two at the end of the month, all may yet be well; but if the rainfall of these months is light and partial, and if it ceases prematurely, the crops form no ear, and they perish and dry up in the warm dry west winds that speedily follow. And it is these crops that furnish the food staples of the agricultural classes of India. H. F. B.

PHYSICAL SCIENCE FOR ARTISTS.[1]

II.

WE next come to the absorption of light. I do not know whether you have had any opportunity yet in your laboratory course of observing the spectral phenomena produced when white light, or say solar light, is absorbed by different substances. The white light is broken up by the dispersion of the prisms into a rainbow band; while it is possible, by one means or another, one substance or another, to filch out of this coloured band some of the constituent colours, now at one end, now at another, sometimes in different parts at once; and when this has been done, the light which finally reaches the eye may be of any colour, as is evidenced by the different colours you see in a stained glass window. This is what happens also by the absorption of our atmosphere, due in all probability in great part to the contained aqueous vapour. The sun is white in the middle of the day and red at sunset. The blue part of the light, which, when all the colours reach us, looks white, has been taken away, and practically nothing but red is left; only certain parts of the spectrum are left. It is easy, after two or three hours' experiments with the absorption of light by different media, to grasp the laws which govern sunset colours precisely, as it is easy in the anatomical school to study the facts relating to the human form, particular muscles and the like. A diligent student will thus have the world of colour at his feet. This can, however, only be done by one interested in physical science, and I think it should be done by anyone who wishes to deal with landscapes or seascapes, anything, in fact, which has to do with the natural world. The results obtained in this way of course come to us pictorially, chiefly in the colour of sky and water and in the colours of clouds, and they are mixed up in pictures by the knowledge, or want of knowledge, of the artist who paints these various reflecting surfaces. The reflecting surface, whether water or cloud, or what not, must not only be true in colour, but perfectly formed, in order to give an absolutely perfect and pleasant picture.

Here I think it is that the need of physical science is greatest, and I do not know, in fact, that there ought not to be some kind of an examination in a College like this which shall insure that anyone who is going to take up the study of art is not colour-blind. This is done in the case of sailors and engine-drivers, and I think it should be done in the case of artists. There are pictures which have apparently been painted by colour-blind people; and of course it should be a subject of great regret that so much skill has been wasted in consequence of such a malformation as this.

It may be, of course, that in some cases, where the thing may be charitably supposed to arise from a physical defect, it is the result of mere ignorance, or want of observing power; but if that be so, then my point is proved, because it is clear that a good scientific training will cause these objectionable, impossible, colours to be gradually eliminated from our exhibitions. On the other hand, when we look at a gallery of pictures, one is so frequently rewarded by the exquisite truth of some of them, that one could very well look over the defects of others, if all thoughts of the possible progress of art achievement were banished from one's mind.

Some of you may perhaps have read Mr. Ruskin's chapter on clouds. The scientific basis of the various cloud forms, however, you will not find there. Now when we consider that in land- and sea-scapes the sky, and especially the clouds, are among the most important reflectors of light, whether white or coloured, the form of the cloud is absolutely of very high importance. If the light is reflected by an absolutely impossible cloud, your delight at the colour, which may be true, is absolutely checked by the treatment of the anatomy of the cloud. Here, again, we touch a distinct branch of physical science. An acquaintance with the various forms of condensation assumed by aqueous vapour under the various conditions of the atmosphere would certainly keep one right where one would be very apt to go wrong. I referred, also, to the reflection of sunlight, whether white or coloured by absorption, by water. Here, I think, is a region where physical science is also helpful. There can be no question that the grandest display of colour in the natural world is a sunrise or sunset, either at sea, or where there is a water surface to bring in a second series of reflection phenomena. As a rule, perhaps, if the water be somewhat land-locked, or at all events not broken up by strong wind, the effect is finer, and this perhaps is one of the reasons, but only one, why the sunsets seen off the west coast of Scotland are so remarkable.

This, however, does not always hold. I have seen a sunrise in the Mediterranean when passing the Straits of Gibraltar twenty years ago, which was so magnificent, that not only is it still present in my mind's eye, but all the sailors who were swabbing the deck at the time ceased work and simply gazed at it entranced. It promised to be a cloudy sunrise, but suddenly the cloud pall melted into mackerel sky, and the sun at rising payed out different colours on the high and low patches; the sea was choppy, and every facet of every wave, and every facet of a facet, being turned to different parts of the sky; these picked up and reflected to the eye different colours, so that every wave looked like a casket of gems.

The red or yellow colours on the clouds depend simply upon the thickness of the atmosphere which the sunlight has traversed to reach them; the colour depends absolutely upon the light received from the sun, and it has nothing to do with the apparent angular distance from the sun in your picture; but while all this change is going on in the clouds the sky itself will be zoned above the horizon from the red to the blue overhead, and in addition to that, you will get the greater luminosity nearer the sun's place. But further than that the sky will not go, because it cannot. At the same height above the horizon you must have absolutely the same sky colour. Now that is a very obvious conclusion. You will always note the greatest possible distinction between the colour of the pure sky and of the clouds. A favourite *sky* colour in sunsets is green. I have seen no green *clouds* except in pictures.

I have noted a few of those pictures this year, which, in my opinion, and I only give it for what it is worth, are remarkable for their truth, or for the absence of it, in different degrees. The numbers are those of the Royal Academy Catalogue, unless otherwise stated:—

Clouds.—Good colour, 351.
Good form, 288, 600.
Good colour and form, 238.
Water.—Good colour, 630, 1029.
Good surface, 682, 759, 1013. New Gallery, 102, 120.

With great deference I must, until convinced to the contrary, hold that much of the colour in the following

[1] Continued from p. 178.

Digitized by Google

pictures is *impossible*—543, 1028, 176, 192, 515; it is bad in 203, 498, 586, 602, 1044, 1071.

The cloud forms in 498, 536, and 966 are unlike anything I have seen in any quarter of the world.

But cloud is not the only thing we have to deal with. There is a still finer form of aqueous vapour which shows itself as *atmosphere;* its function is to soften distant outlines, to gradually assimilate colours, laying, so to speak, its own upon them, and then, again, to soften even this. So that distant vistas of hills and vales first become blue in prevailing tone, but the most distant ones lose this, and fade to a more neutral tint.

These things this year are admirably rendered in 1130. 293 offends by the impossible hardness of the hill on the right of the picture.

To most of you the terms selective *absorption* and selective *reflection* of colour are familiar; of the latter an admirable study is to be found in 1062. For reflection badly managed, study 145 in the New Gallery. The artist seems to be under the impression that some birds have a special capacity for reflecting colour.

Of special studies of various natural objects, I think the following in the German Exhibition are worth examination: a glacier (287); cloudy moonlight (433); careful study of light-grading (but sun should be more luminous in the latter) (52, 343).

It is not a little singular that we should find such a close association between bad cloud forms and bad colour. It was a true instinct which led Mr. Ruskin to treat of these matters in his "Modern Painters," but why did he not go further into the real basis—the real grit of it all, instead of confining himself to the mere fringe of these great subjects? It was, I expect, because the possible connection between science and art was less recognized then even than it is now. But is it too late? No one could touch the questions still with more sympathy than Mr. Ruskin.

But to come back to the pictures. Almost, if not quite as good as 600, is No. 50 in the German Exhibition We find in 630 a careful study of colour. The most wonderful colour which can be got on nearly still water is that you sometimes see at sunrise or sunset with a good green or yellowish sky near the horizon, and a perfectly blue sky overhead. In that case every unit of the surface (every undulation) will reflect to your eye a certain amount of horizon-light and a certain amount of blue sky, and the total result will be a sea of molten steel. Another point in this connection is this: if your surface is even, you can get a reflection of this kind from several surfaces besides water. I was in Egypt last winter, and I saw a wonderful sunset, looking out from the little quay at Ismailia. The sand of the desert lay beyond and round the water in the foreground, which was more or less bluish; the lake, in fact, is bounded by sandbanks of no great elevation, the canal coming in at one end and running out at the other.

In the day-time in full sunshine the sand is yellow, as yellow as it can be, and at sunset it is grey-white. There is nothing very remarkable in the sky, but the intense blue in the sky overhead. There is no aqueous vapour to absorb, and therefore there is no colour. But wait for the after-glow! when you get sunlight, reflected from the clouds or sky, which reaches your eye after two transmissions through the lower air; then you can get colour, and you do get it. What you see is the most exquisite violet halo, and the colours with which we are familiar here more or less; but the striking thing is the intense violet halo in the sky, and the warming up of colour till the sunset place is reached. Well, now, what is the effect of that upon the landscape? Everything is turned green, for the simple reason that the only constituent common to the colour which reaches, and is reflected most readily by, the sand, is the tint of green: the sands change, as if by magic, into a wonderful chlorophyll green. Now, I venture to think that the artist who endeavours to work out problems of this kind will be more likely to paint a beautiful picture than the one who copies nature merely, and this brings me into strict harmony with the Academy motto. It seems to me that physical science may in this way, if associated with the study of art, give us new possibilities in the art future that will transcend anything that we know of now, and the time will certainly come, ultimately, when the highest art will result from the study of natural science and the science of the human form.

Seeing that already artists spend years in the study of only one part of the field of observation, they must surely in time come to the conclusion that it would be better to annex other branches.

It would not be right if I concluded what I have to say without calling attention to the important remarks made by Mr. Briton Rivière, on science in relation to painting, at the Edinburgh Art Congress:—

"Whatever may have been done in other lines of human energy during the Victorian age, there can be no question that its most remarkable achievements, both theoretical and practical, have been those of science. . . . The art of the painter has not escaped its influence. On one side, and a very important one—that of realism—the side which furnishes the language—*i.e.* the signs and symbols which express the idea of the artist—there is a wide front open to the influence of science; and on that side art has not been slow or unwilling to follow the advice of science, or ungrateful for the valuable help it has afforded. According to my theory, this supremacy of science would have influenced art under any circumstances, but it has been able to do so through the very method and language of art itself.

"Will this influence help or retard the influence of art? My answer is, it may do either, according to the manner in which it is received and used by the artist. If the painter resolutely holds the belief that painting is a language, and a work of art the expression of an idea, and uses science, and all that it has discovered and teaches, to enable him better to understand his signs and symbols, viz. the material facts of nature, so that by means of them he may express himself correctly, just as a writer has behind him the philologist to busy himself about the derivation and meaning of words, and the grammarian to show him how to place these words so as to produce the meaning he requires—if, I say, the painter so receives and uses the knowledge and appliances of science, then I think the cause of art will be much advanced by science, and works produced under its influence will be stronger and richer than they could possibly have been without it. On the other hand, if the painter allows this scientific knowledge of the material or realistic part of his work to obscure the purely artistic or ideal part of it, to obscure instead of to intensify the *idea;* and if, carried away by the material wonders of the 'thing' which science has unfolded, he forgets the 'thought' altogether, then assuredly, however true he may have shown himself to be to the cause of science, that of art will suffer at his hands—indeed, may be lost altogether. For I feel sure that most of my brother artists will agree with me that it is possible for a picture to be scientifically true and have no art at all in it: and, on the other hand, to contain several scientific blunders and yet be a great work of art."

It will be seen, then, that I have ventured to-day to preach no new doctrine to you: even my gloss on the Academy motto is endorsed by Mr. Briton Rivière.

But I can go further than this, and quote Prof. Helmholtz in support of the gloss. You should all read his admirable lecture "On the Relation of Optics to Painting."[1] In it he remarks, "The artist cannot transcribe Nature: he must translate her;" and he adds, "This translation may give us an impression, in the highest

[1] "Popular Scientific Lectures," Helmholtz, 2nd Series, p. 135. (Longmans. 1881.)

Digitized by Google

degree distinct and forcible, not merely of the objects themselves, but even of the greatly altered intensities of light under which we view them. . . . Thus the imitation of Nature in the picture is at the same time an ennobling of the impression on the senses."

Let me congratulate you on the fact that here, at all events, the importance of physical science in its relation to art is not forgotten. J. NORMAN LOCKYER.

LUMINOUS CLOUDS.

IN an article contributed to NATURE on November 20, 1890 (vol. xliii. p. 59), Herr O. Jesse (of the Royal Observatory of Berlin) gave an account of his observations of luminous clouds. He has recently submitted to the Prussian Royal Academy of Sciences a record of later work: and, as the subject is one of considerable interest, it may be worth while to translate his paper.[1]

With regard to the results, already briefly noted, obtained in the summer of 1890, I have now to report more precisely, that with the help of the grant made by the Academy of Sciences we were able, during the period when the phenomenon appeared, to secure a collection of photographs which afford rich material for study.

On this as on previous occasions the clouds were visible only between the end of May and the beginning of August. They appeared for the first time, in 1890, on May 26; for the last time—and then there was only a feeble trace of them—at the beginning of August. The phenomenon, therefore, was seen within nearly four weeks of the summer solstice—before and after it—but chiefly after it.

Since my last report, I have received confirmation of the statement that the time when the phenomenon appears in the southern hemisphere has a corresponding relation to the summer solstice there. Unfortunately, however, more precise facts with regard to place, &c., in the southern hemisphere, are still lacking.

During the period between May 26 and July 24, 1890, we obtained altogether 180 photographs of luminous clouds at Steglitz, Rathenow, and Nauen, and at the Observatory of Urania, Berlin. Of these photographs, 75 are suitable for the determination of height, inasmuch as they were secured at the same time in at least two different places. Thirty of the photographs may be used for the determination of the speed and direction of the movements of the clouds, because their representations of the clouds were taken at proper intervals at one and the same place. The remaining photographs are adapted for investigations relating to the dimensions of the clouds and their structure.

The phenomenon was again less bright than it had been in the preceding year. Only when the atmosphere was exceptionally transparent was there an approach to the former brilliancy. The aggregations of these masses of particles are obviously becoming thinner, as may also be perceived from the more distinct appearance of certain relations of structure, like the ridge and rib formations (wave formations) mentioned in my last report. Formerly these were concealed by superposition and apparent interference of a greater richness of analogous strata: now the characteristic lines of the configurations consisting of these ridge and rib formations present themselves more simply and in greater isolation.

It has now been proved more successfully than before that the ridges or longitudinal strips lie parallel to, while the ribs or cross strips are almost at right angles to, the direction of the movement of the entire cloud. Further, we made on different days several series of measurements of the distances of the ribs (wave-crests) from one another with the following groups of results:—

		Kilom.
Mean value of the distances of	9 wave-crests ...	8·3
,, ,, ,,	10 ,, ...	9·9
,, ,, ,,	10 ,, ...	8·4
	Average ...	8·9

Especially striking, last summer, was the difference between the clearness with which the clouds appeared in the morning hours, and that with which they appeared at the corresponding times before midnight.

With regard to the height of the luminous clouds in the summer of 1890 the measurements, so far as they were definitely calculated, gave the mean value of 82 kilom., agreeing almost exactly with the value of nearly 83 kilom., deduced from my photographs of 1889.

The persistence from year to year—now for the first time shown with sufficient accuracy—of the distance, and therefore of the position of the level surface of the phenomenon, would alone deserve to be recorded as a scientific fact of great importance.

As for the speed and directions of the movements, it was again found that the chief component of the movement was directed from east to west, and amounted to nearly 100 metres in the second, while the speed of the revolution of the zone of the earth above which the clouds were placed is about 240 metres in the second from west to east.

There was also a smaller and variable component in the direction of the meridian. This was directed from north to south at the times at which we have hitherto obtained tolerably secure determinations of movement.

The points of view from which the phenomenon of luminous clouds, on the ground of the observations hitherto made, is to be regarded, are already numerous. There is still, however, a wide field for research in connection with the questions, What are the forces which make the phenomenon appear chiefly in the morning hours? and, What is the nature of those forces which cause the movement of the clouds to be mainly from the north-east, and drive them from the northern to the southern hemisphere and back again? Then the question as to the height of the phenomenon in different latitudes is probably of great importance for the constitution of our atmosphere; and not less interesting is the question relating to the material of which the luminous clouds are composed. Unfortunately the interest taken by the scientific world in this remarkable phenomenon is in general so small that during the short time the phenomenon will probably present itself we can scarcely expect to obtain for these questions answers that shall be to any considerable extent satisfactory.

WILHELM EDUARD WEBER.

THE venerable physicist, Wilhelm Eduard Weber, whose death on June 23 we shortly announced last week, was born at Wittenberg on October 24, 1804, the second of three sons of Michael Weber, Professor of Positive Divinity at Wittenberg. He studied at the University of Halle, where Schweigger was then Professor of Physics; he took his Doctor's degree in 1826, became Privatdocent in the following year, and Professor-Extraordinary of Physics in 1828. In 1831 he was called to Göttingen to succeed Johann Tobias Mayer in the Chair of Physics, and remained there till 1837. Among other results of the death in this year of King William IV., there came about serious changes in the University of Göttingen. Queen Victoria being excluded from the throne of Hanover, by the operation of the Salic law, her uncle, Ernest Augustus, Duke of Cumberland, became King of Hanover. This prince held high views as to the

Digitized by Google

powers of hereditary rulers. In his view the narrow liberties enjoyed by his subjects, under the Constitution reluctantly granted by William IV. in 1833, were excessive and intolerable. He suspended the Constitution, and thereby called forth vigorous protests from Dahlmann and other Professors of the Hanoverian University. As a punishment, seven of them—Dahlmann, Weber, the two Grimms (Jacob and Wilhelm), Albrecht, Gervinus, and Ewald—were ejected from their chairs, and Gervinus, Dahlmann, and Jacob Grimm were even expelled from the country. From this time Weber lived for some years in retirement, but in 1843 he accepted the Professorship of Physics in Leipzig (in succession to Fechner), and in 1849 he returned to his former position in the University of Göttingen. He was in Göttingen at the time of his death.

Wilhelm Weber's eldest brother, Ernst Heinrich, was the celebrated Professor of Anatomy and Physiology at Leipzig. He was born at Wittenberg in 1795, and died at Leipzig in 1878, having been elected a Foreign Member of the Royal Society of London in 1862. The youngest of the three brothers, Eduard Friedrich, was also highly distinguished as an anatomist, and held office for many years in the University of Leipzig.

Weber's first contribution to science at once took rank as a scientific classic, a position it is likely to keep for many years to come. This was "Die Wellenlehre auf Experimente gegründet," a volume of 574 pages, and 18 copper plates, nearly all engraved by the authors, published in 1825 by the brothers Ernst and Wilhelm Weber, and embodying the results of numberless original experiments and observations. One of the most striking results of these investigations was the discovery that, when a regular series of waves follow each other along the surface of water, the particles at the surface describe vertical circles whose plane is parallel to the direction of propagation of the waves, and those lower down ellipses of which the vertical axis becomes smaller and smaller with increasing depth. As to the composition of this work, the authors say that it grew up as the result of such constant and intimate communication between them with regard to all parts, that it is impossible to assign to either of them the separate authorship of any distinct portions.

For several years Weber continued to occupy himself mainly with questions of acoustics, on which he published various papers of importance. In 1833 he published, in conjunction with his brother, Eduard Friedrich, a memorable investigation into the mechanism of walking ("Mechanik der menschlichen Gehwerkzeuge").

But it is chiefly by his magnetic and electrical researches that Weber's place in the history of science is marked. These are contained for the most part in the "Resultate aus den Beobachtungen des magnetischen Vereins," published by Gauss and Weber from 1837 to 1843, and in Weber's "Elektrodynamische Maassbestimmungen" (published in collected form in 1864, though the first paper dates from 1846). In this series of papers Weber showed for the first time how methods of absolute measurement, analogous to those which Gauss had very shortly before shown to be applicable to magnetic measurements, could be extended into the region of electricity. Before this time Ampère's splendid discoveries as to the laws of the mutual forces between magnets and conductors traversed by electric currents, or between two such conductors, had been made known, and G. S. Ohm had established once for all the relations between electrical resistance, electromotive force, and strength of current; but, nevertheless, there was as yet no settled system for the measurement and statement of electrical quantities themselves. Until Weber's time electrical measurements were merely comparisons between magnitudes of the same kind: the resistance of one conductor could be compared with that of a particular piece of wire, the electromotive force of one battery could be compared with that of another; but that the value of an electrical quantity could be stated without reference to any quantity of the same kind, and in terms not involving any physical constants but the units of length, time, and mass, was as yet an entirely new conception. Weber, however, not only showed that such a system of measurements was theoretically possible, but in a series of most masterly experimental investigations he showed how it could be practically carried out. Our countryman Sir William Thomson was one of the very first men of science to recognize the fundamental character and far-reaching importance of Weber's work; and owing mainly to his clear-sighted advocacy of the absolute system of measurement, this system was from the first adopted as the basis for the operations of the British Association Committee on Electrical Standards, appointed originally in 1862. This system has now become so familiar to electricians, and is taken so much as a matter of course, that it requires some mental effort to recall the state of science when it did not exist, and to appreciate the intellectual greatness of the man to whom it is due. If we consider method and point of view, rather than acquired results, it is not too much to say that the idea of absolute measurements, underlying as it does the conception of the conservation of energy, constitutes the most characteristic difference between modern physics and the physics of the early part of our century. And to no one man is so large a share in this great step due as to Wilhelm Eduard Weber.

Weber was a Corresponding Member of the Institute of France. He was elected a Foreign Member of the Royal Society in 1850. G. C. F.

A SOUVENIR OF FARADAY.

THE following letter, written by an old friend of Faraday's and of mine, long since dead, may interest your readers, now that we are celebrating the centenary of Faraday's birth. It came in reply to one in which I asked Mr. Ward's assistance in preparing an obituary notice of Faraday for the *Chemical News*.

WILLIAM CROOKES.

Cornwall, August 30, 1867.

DEAR CROOKES,—I should be proud indeed to be the spokesman of the chemical world in doing honour to Faraday's illustrious name on the occasion of his accession to immortality.

But I should not dare to meddle with the laurels on so august a brow, without many days and nights of earnest research and meditation, to fit me for summing up, without omission, the splendid list of his imperishable labours.

Only in this reverential spirit of earnest solicitude to do aright, which is, if I mistake not, the philosophical counterpart of prayer—of the religious feeling—could so solemn a duty be fitly undertaken.

Only with the aid of other minds, kindred with Faraday's in genius, and filled with the light of his manifold discoveries, could any one man's mind become an adequate mirror to reflect the gigantic Shadow that has just passed to its place in futurity.

For the present it is my fate to fulfil much humbler duties—which, having undertaken, I have no right to set aside. For duty must still be done, even when such appeals as yours set the wings of the caged lark trembling, and point him upwards to his barred out home.

I must remain, therefore, a unit among the millions whose hearts do silent homage to the illustrious dead; and can but watch from afar the starry coronation of which you invite me to be minister.

So best, perhaps. For, after all, the name and fame of

Digitized by Google

Faraday transcend all pomp of celebration, all burning words of praise. For whose the pen to weave so bright a glory as that electric fire which glows, through all the ages, round his brow, who first drew lightning from the lodestone, as Franklin drew it from the sky?

In the moment of separation that little spark breaks forth—instantaneous yet eternal. It is but one vivid point of the radiance that encircles his name, yet of itself it is glory enough.

From that spark a new branch of science has sprung, and under its creator's name, were it mine to carve his epitaph, these three should be the chosen words:—

FULMEN ERIPUIT FERRO!

Ever yours faithfully,

F. O. WARD.

NOTES.

WE print elsewhere an account of the fourth annual meeting of the National Association for the Promotion of Technical and Secondary Education. After the meeting an important conference was held, and it is now hoped that all the influences which are tending towards the establishment of a proper system of technical instruction in England may soon be thoroughly organized. Next week we shall have something to say about the work of the conference and about the Association's report.

THE *conversazione* given by the President of the Institution of Electrical Engineers, Prof. Crookes, F.R.S., and Mrs. Crookes, on Monday evening, was brilliantly successful. It was held in the galleries of the Royal Institute of Painters in Water Colours, Piccadilly. There were about 800 guests, among whom were many eminent men of science.

ON Tuesday evening the Fellows of the Royal Meteorological Society and their friends dined together at the Holborn Restaurant, to celebrate the entrance of the Society upon its new premises in Great George Street, Westminster. Mr. B. Latham, the President, occupied the chair. Mr. A. R. Binnie (Engineer to the London County Council) proposed "The Royal Meteorological Society," and Mr. G. J. Symons responded. Mr. Latham, replying to the toast of "The President," referred to the enormous amount of records in the possession of the Society. All they now wanted was a few more members. However, they had gone on increasing, and were now in a prosperous state, as they had been able to collect from the members of the Society a considerable sum of money, which had been funded, and the interest on which would meet the expenses of the new establishment. The Society now possessed one of the finest meteorological libraries in the world, and one which would be of enormous value to future generations.

WE are glad to note that the Marine Biological Association have now only three unoccupied tables. Many investigators are taking advantage of the facilities offered them at Plymouth.

THE Exhibition Committee of the Photographic Society of Great Britain announce that the annual exhibition of that Society will be held at the Gallery of the Royal Society of Painters in Water Colours, Pall Mall East, from Monday, September 28, until Thursday, November 12 next. The exhibition will be open daily (Sundays excepted) from 10 a.m. to 5 p.m., and on Monday, Wednesday, Thursday, and Saturday evenings from 7 p.m. to 10 p.m. Medals will be awarded for artistic, scientific, and technical excellence of photographs, for lantern transparencies, and for apparatus.

THE Pacific Postal Telegraph Company had lately a gathering of some 500 guests at the opening of a new telegraph office in San Francisco. After shortly describing the various instruments, Mr. Storrer, the superintendent, said he was often asked how long it took to telegraph to different places and get a reply. He would therefore now send a telegram to Portland, New York, Washington, Seattle, Tacoma, Canso (Nova Scotia), and London, inquiring about the weather. The first reply came from Portland in 3 minutes, "Weather fine"; the next from New York in 3 minutes 10 seconds, "Misty and warm"; Washington in minutes 11 seconds, "Misty and warm"; Seattle in 3 minutes 21 seconds, "Misty and calm"; Tacoma in 3 minutes 28 seconds, "Misty, cool, and calm"; Canso, Nova Scotia, in 4 minutes 20 seconds, "Cold and misty"; while the answer "Misty and cold" came from London in 6 minutes 22 seconds.

THE Governors of the Royal Holloway College have appointed Miss M. W. Robertson to the Resident Lectureship in Natural Science. Miss Robertson, who is now a lecturer on the staff of Alexandra College, Dublin, has taken the degrees of B.A. and M.A., with high honours in chemistry and physics, at the Royal University of Ireland, and has also gained the University Studentship in Experimental Science.

THE Education Department has issued a memorandum, by Mr. J. G. Fitch, on the working of the free school system in America, France, and Belgium.

THE death of M. Rodolphe Kœppelin, a distinguished chemist, is announced. He was born at Colmar in 1810, and from 1828 to 1859 held the Chair of Physics and Natural History at the College of his native town. For many years he was intimately connected with the Agricultural Society of the Upper Rhine, and, as a chemist, he was able to render great services to the agriculturists of his department. After the Franco-German war, M. Kœppelin quitted Alsace, and settled in Paris, where he was regarded as one of the most eminent members of the Alsatian colony.

IN another part of the paper we print a report, by Herr O. Jesse, of his observations of luminous clouds in the summer of 1890. We learn from Herr Jesse that on the night of June 25–26 last the luminous clouds were again very visible at Steglitz and Nauen, and that they were photographed eight times simultaneously at these two places. Writing to us from Sunderland on July 1, Mr. T. W. Backhouse says there was a fine display of the luminous clouds during the previous night, their motion being, "as usual, from a north-easterly direction." Mr. D. J. Rowan informs us that on the same night, from 11.30 p.m. to 12.30 a.m., the clouds, as seen at Kingstown, co. Dublin, "appeared well-developed on a polar arc of 30° and at a mean altitude of 5°." They had been faintly visible at Kingstown on June 3, 7, and 9. It is astonishing that no observer seems yet to have had energy and intelligence enough to take spectroscopic photographs of these striking phenomena.

ACCORDING to a telegram from Melbourne, dated July 4, the Swedish-Australian Antarctic Committee of the Victorian branch of the Royal Geographical Society, which was formed to raise subscriptions in order to take advantage of Baron Nordenskiöld's offer to equip an expedition to the Antarctic regions, announces that a sum of £3000 only is required to complete arrangements, and that there is every prospect of the expedition starting in about fifteen months' time. It is expected that the expedition, in addition to its geographical and other scientific discoveries, will be the means of opening up extensive whale and other fisheries in the Antarctic seas.

WE learn from the *Botanical Gazette* that Lieut. R. E. Peary, of the U.S. Navy, proposes to reach the North Pole on foot through Greenland, starting from Whale Sound, and

Digitized by Google

expecting to be absent from 1½ to 2½ years. He states that the region about Whale Sound is rich in Arctic plants, Kane having brought over 106 species of Phanerogams and 42 of Cryptogams, several of which were new, but that very little has been done in its investigation since that time.

THE danger of using arsenical preparations for the poisoning of plants is illustrated by the fact that Dr. B. L. Robinson, assistant in the Gray Herbarium, Cambridge, U.S.A., has been compelled to resign his position owing to ill-health resulting from this cause. It is stated that the poisoning of plants has now been entirely abandoned in the herbarium; the tightness of the cases, and constant handling of the sheets being relied on to preserve the specimens.

MR. SPENSER LE MARCHANT MOORE has been appointed botanist to the Matto Grosso Gold and Explorations Concessions Expedition, which is about to depart for Brazil.

A NEW botanical journal has just been started, devoted to the diseases of plants, *Zeitschrift für Pflanzenkrankheiten*, edited by Dr. Sorauer, and published at Stuttgart.

DR. JOHN MURRAY contributes to the *Journal of Botany* for July a very interesting account of the Clyde sea-area, its physical characters, and the chief features of its natural history. This sea-area is a natural system of deep-sea basins or lochs in the west of Scotland, communicating southward with the Irish Channel by a single opening between the Mull of Cantyre and the shores of Wigtown and Ayr. It has a water surface of about 12,000 square miles; its greatest depth is 107, and its mean depth about 29 fathoms. There is a great variety in the pelagic fauna and flora in the surface and intermediate layers of water, the abundance and the species of organisms varying in the different layers according to the seasons, and even in different years. There is likewise a great variety in the bottom-living fauna and flora, which varies according to the nature and depth of the bottom in the different parts of the area. In some of the deeper lochs a few animals are met with which do not usually occur in more open situations around our coasts till a depth of 200 or 300 fathoms is reached. Some of these forms are limited to one loch on the west coast; for instance, *Conchaecia elegans*, which is abundant in Loch Etive. This form has never been taken in any of the lochs of the Clyde sea-area, although *Euchaeta norvegica*, with which it is associated in Loch Etive, occurs abundantly in Upper Loch Fyne and Loch Goil. *Nyctiphanes norvegica* and *Boreophausia Raschii*, which are abundant in the upper lochs of the Clyde sea-area, do not, on the other hand, occur in Loch Etive.

THE French Minister of Public Works has addressed a circular letter to civil engineers, asking them to use their influence to protect prehistoric monuments from the injury often done by ignorant proprietors. It seems that little respect is shown for such monuments in some parts of France. *La Nature* speaks of a proprietor who sold "a magnificent dolmen," which was to be transformed into "a tomb in a cemetery."

IN his report, for 1890, to the trustees of the Peabody Museum of American Archæology and Ethnology, Prof. F. W. Putnam, the Curator, records that in no former year had the friends of the Institution been so generous in giving aid. Gifts for current expenses were received which, in the sum total, exceeded the regular income from the funds; and Mrs. Mary Copley Thaw, of Pittsburg, added no less than 30,000 dollars to the amount held in trust, this sum being set apart as an endowment for a fellowship.

AN apparatus has been recently constructed by M. Ducretet, for getting quickly in the laboratory a fall of temperature 70° to 80° C. below zero, by means of the expansion of liquid carbonic acid. The inner of two concentric vessels contains, in alcohol, a serpentine metallic tube communicating through a tube with two stopcocks, with the carbonic acid reservoir outside, and opening below into the annular space round the inner vessel, in which are some pieces of sponge impregnated with alcohol. This two-walled vessel with coil is inclosed in a box. One stopcock being opened wide, the other slightly, the carbonic acid passes through the coil as snow, and turns to gas, with strong cooling effect, and any of it not vaporized in the coil is dissolved in the alcohol of the sponge. The gas escapes through a tube passing through the outer box. The instrument, called a *cryogen*, is represented in *Cosmos* of June 27.

EXPERIMENTS have lately been made by Herr Regel (*Bot. Centralb.*) with reference to the influence of external factors on the smell of plants. In the front rank appears the direct and indirect influence of light on the formation of etheric oils and their evaporation. In the case of strongly fragrant flowers (as *Reseda*) heat and light intensify the fragrance, which in darkness is lessened without quite disappearing. When the whole plant was darkened, those buds only which were before pretty well developed yielded fragrant flowers; the others were scentless. If, however, only the flowers were darkened, all were fragrant. Other plants open their flowers and smell only by night (as *Nicotiana longiflora* and *Nycterinia capensis*). When these plants were kept continuously in the dark, they, in course of time, lost their scent, as they lost their starch. On being brought into light again, both starch and fragrance returned. Besides light, respiration has a decided influence on the fragrance. Nycterinia, inclosed in a bell jar with oxygen, behaved normally, but with hydrogen the flowers did not open, and had no fragrance. In general, the opening of flowers coincides with their fragrance, but there is no necessary connection between these phenomena.

A NEW antiseptic, said to have certain advantages over those hitherto in use, has been brought before the French Academy of Medicine by Prof. Berlioz, of Grenoble: extreme solubility, harmlessness, efficacy, and rapidity of action are claimed for it. It is called *microcidine*, and is a compound of naphtol and soda, is neither poisonous nor irritant, is twenty times as active as boric acid, and much more soluble than thymol, carbolic acid, &c. Microcidine has the form of a greyish-white powder. In a solution of 3 grammes per litre it is very slightly coloured, but it does not stain either the hands or bandages. For family use it is said to be of great service.

MOST Russian geologists are now of opinion that the boulder-clay which covers the whole of Middle Russia is nothing but the bottom moraine of the ice-cap which, during the Glacial epoch, extended from Scandinavia and Finland to the latitude of Kieff and Poltava. A couple of years ago, Prof. Pavloff, while working in connection with the Geological Survey in Nijni Novgorod, indicated some traces of an inter-glacial milder period among the glacial deposits covering the province. Like indications have been noticed in Poltava and Tchernigoff. New data to confirm this view are now given by N. Krischtafovitch in the *Bulletin* of the Moscow Naturalists (1890, No. 4). After a careful exploration of the Quaternary deposits at Troitzkoye—a village on the Moskva River, seven miles to the west of Moscow, the diluvial deposits of which have very often been mentioned since Prof. Rouillier's and Murchison's times—the Russian geologist came to the conclusion that these deposits are indicative of an inter-glacial period, during which Middle Russia had a flora and fauna much like those which exist now, but with the addition of the Mammoth. The layers described by M. Krischtafovitch as inter-glacial are of lacustrine origin; they are covered with undoubtedly glacial deposits, and they are

deposited over glacial sands containing boulders of northern origin. Further research, however, is wanted. It is certain that, both during the first invasion of the ice-cap and its ultimate retreat, its outer limits must have been subject to very great oscillations. We know that, in Greenland, parts of valleys which for hundreds of years were covered with vegetation, are sometimes invaded again with ice, and that lacustrine deposits must arise in this way between purely morainic deposits. The same must have taken place in the ice-cap of Russia; and the oscillations of the glaciers on the outer border of a large ice-cap are on on a much greater scale than the oscillations of isolated glaciers in Alpine regions. When the ice-cap began to invade Middle Russia, its advance was undoubtedly accompanied by many oscillations; regions invaded by ice must have been set free of ice for a succession of years, and they became the seats of lakes. The same oscillations must have taken place during the retreat of the ice-cap. The existence of a warmer inter-glacial period, therefore, though not improbable in itself, can be proved only by means of a very wide exploration of the boulder-clay, and such an exploration has not yet been made.

THE system of meteorological observations in Alsace-Lorraine has now been centralized, a meteorological service for the Reichsland having been established. The control of the new service has been intrusted to the geographical seminary in connection with the Strassburg University, and has been definitely undertaken by Dr. H. Hergesell, who desires to organize the service in accordance with the best modern ideas. A meteorological record will be issued as a part of the German meteorological *Jahrbuch*.

A REMARKABLE series of three hailstorms which passed over Graz on August 21 last year, about 5, 6, and 7 p.m. respectively, has been carefully studied by Prof. Prohaska (*Met. Zeits.*) Stones from 1·6 to 2·4 inches in diameter fell in the town, forming a compact ice-mass, in some places about 3 feet thick, and a white cloud of vapour formed over the ice. It is noteworthy that all three storms took a nearly quite straight path over mountain, valley, and plain; no influence of mountains on the direction was perceptible. The advancing strips of hail were 10 to 14 km. in width; the first went 173 km. east-south-east; the second and third almost exactly east; one 110 km., the other 201 km. The 70 km. stretch of country from Stiwoll over Graz to the Hungarian border lay in the path of all three, so the ice deposited by the first offered no hindrance to the others. Mountains seem to have affected the velocity, if not the direction, of the storms; they were passed more slowly than plains or undulating ground (35 km. an hour against 49 km.). A violent wind came out from the hail column, a west or north-west wind in front, north on the south side. But further out, in front especially, there was a well-marked air-current towards the hailstorm; and this was especially strong on the lee side of a mountain. Whirling movements were not observed, and there was but little thunder and lightning. The falls of temperature were very pronounced: *e.g.* in the first storm from 26° C. to 5°. The barometer went down before each hailstorm, then suddenly rose.

AT the meeting of the Linnean Society of New South Wales on May 27, Mr. Henry Deane stated that in April, while travelling by night through the Big Scrub in the Richmond River District, his interest was aroused by the remarkable effect produced by luminous insects which abounded by the roadside. Specimens were secured and sent off in the hope that they would arrive in time to be exhibited at the previous month's meeting, but they came a day too late, and in the meanwhile had died. From their general resemblance to the larvæ of *Ceroplatus mastersi*, Sk., which are also phosphorescent, Mr. Fletcher, who had seen the specimens forwarded, was of the opinion that these were very probably also dipterous larvæ. Mr. David made some remarks on certain luminous organisms which he had observed in old coal-mine workings in Illawarra, the identification of which it was hoped would not long be postponed.

MESSRS. CASSELL AND CO. have issued Part 33 of the "New Popular Educator," which is to be completed in forty-eight parts. The present number includes, besides the illustrations in the text, a coloured representation of insectivorous plants.

THE first volume of Messrs. Whittaker's new "Library of Popular Science" will be an elementary introduction to astronomy, by Mr. G. F. Chambers. The volume will be ready in the course of a few weeks, and will shortly be followed by others.

AN interesting report, by Mr. Campbell, of the British Consular Service in China, has been issued by the Foreign Office. It is the record of a journey of over 1300 miles in districts in Northern Corea, many of which have never before been visited by Europeans. Mr. Campbell started from Seoul, the capital, and crossed the peninsula to the treaty port of Won-san (Gensan), and thence pursued his way along the east coast around Broughton Bay, whence he turned north-eastward, crossing the Yalu River to Päik-tu-San, known to Europeans as the Long White Mountain, and already visited by Messrs. James, Fulford, and Younghusband. The return journey was partly over the same ground, but on arriving at Won-san Mr. Campbell recrossed the peninsula, and so made his way to Seoul. Besides the ordinary record of this journey Mr. Campbell gives a great amount of information on various subjects connected with Corea. The chief amongst these is a most interesting section on the prevalence of Buddhism in the peninsula, and one on the agriculture and productions. He gives a good deal of information in regard to the geography of Northern Corea, and also of the gold production of the country. That Corea contains gold-bearing strata has long been known through the export of gold-dust from the ports, but from Mr. Campbell's report it appears that gold-fields do exist in considerable numbers, and that some of them are worked with the imperfect native methods. There seems no doubt that, if circumstances were favourable to the proper scientific working of the Corean gold-fields, the country would be one of the principal producers of the precious metal in the world. Education in the country seems to be at a very low ebb, and is confined to a knowledge of Chinese. All energy and enterprise is crushed out by an all-pervading tyrannical officialism, and poverty and squalor are universal.

THE new reports of the Inspectors of Sea Fisheries are interesting chiefly for the observations of Mr. Fryer on the oyster fisheries. He mentions the appearance of a curious disease in the neighbourhood of the Thames estuary, in the course of which the shells become so rotten that they will not bear the pressure necessary to open them. The oysters themselves were in good condition, but their round shells, which were muddy, were completely tunnelled in all directions, while the flat valves, which were clean, were uninjured. This points to the conclusion that the ravages were caused by some enemy working from below. The borings were not, Mr. Fryer says, those of either *Cliona* or whelk-tingle, and it seemed probable that they were the work of a minute Annelid which was present in abundance in the interstices of the shells, and in the adherent mud. In a further example sent to him in June no worms were present, although the oyster-shells were similarly undermined; but their place was taken by larvæ closely resembling, if not identical with, those of the worm *Polydora ciliata*. A means of guarding against its ravages, suggested by Mr. Fryer, is the use of an apparatus recently invented by M. Bouchon Brandély, and employed in some of the French oyster *parcs* for the pur-

Digitized by Google

pose of facilitating the growth of oysters. This consists of a series of shallow flat baskets or trays of wire-netting on an iron frame, about 4 inches deep and 2 feet square, placed in tiers, and held together by two iron bands, the number depending on the depth of water in each case. These are either fixed to the soil, or suspended from rafts or other floating bodies, by which means depths of water otherwise inaccessible can be utilized. The other advantages claimed for the apparatus are economy of space in "planting" oysters, and of labour in collecting them, protection of the oysters from five-fingers, and from contact with unsuitable soil, and their exposure on all sides to the free circulation of the water, resulting in more rapid and regular growth, and a greater tendency to depth of shell than under the most favourable of ordinary circumstances. In the case of beds infested with the boring worm referred to, the trays in question would in all probability afford a ready means of placing the oysters beyond the reach of these marauders. The convenience of such appliances, especially in cases where French oysters are laid down temporarily on English beds, to be afterwards transferred to other grounds, *e.g.* during the winter, would probably be found to be very great.

AT a meeting of the Chemical Society held on June 18, a paper was read by Ludwig Mond and F. Quincke, on a volatile compound of iron and carbonic oxide. The authors describe experiments from which they conclude that iron forms a volatile compound with carbonic oxide of the formula $Fe(CO)_4$, corresponding to that of nickel. Very finely divided iron—obtained by reducing iron oxalate by hydrogen at a temperature but little exceeding 400°, and allowing it to cool to 80° in hydrogen—when heated in an atmosphere of carbonic oxide gave a gas which burnt with a yellow flame; and on passing the gas through a heated tube a mirror of iron was formed at between 200° and 380°, while at higher temperatures black flakes of iron and carbon were deposited. Only about 2 grams of iron, however, were volatilized after six weeks' treatment of 12 grams of the metal; it was necessary every five or six hours to interrupt the operation, and to re-heat the iron to 400° in hydrogen during about twenty minutes. When passing carbonic oxide at the rate of about 2½ litres per hour, not more than 0·01 gram of iron was volatilized, corresponding to less than 2 c.c. of the compound $Fe(CO)_4$ in a litre of gas. The authors have effected an analysis of the compound by passing the mixture of gases into mineral oil, boiling between 250° and 300°, and heating the solution so obtained to 180°; iron free from carbon is then deposited and carbonic oxide gas is evolved. Five analyses are quoted, the results of which give a ratio of Fe : CO, varying only from 1 : 4·03 to 1 : 4·264. Dr. Armstrong said that the authors' discovery was extremely interesting on account of the explanation which it might be held to afford of the permeability of iron by carbonic oxide at high temperatures, as well as to the production of steel by the cementation process, to which Graham had drawn special attention. Just as platinum was permeable by hydrogen and silver by oxygen at high temperatures, so iron was permeable by carbonic oxide; it might be supposed, in each case, because a dissociable compound of the metal with the gas was formed. Prof. Thorpe drew attention to the value of the experiments in connection with the production of steel by the cementation process, and stated that he had recently observed that platinum had the property of causing the separation of carbon from carbonic oxide. Mr. Mond said they had refrained from discussing the application of their discovery in the directions indicated, as the compound was only obtained at low temperatures. Dr. Armstrong said this might well be the case; but as Mr. Mond and Dr. Quincke had established the all-important fact that iron had a specific affinity for carbonic oxide, the argument he had used would apply, although the compound might not be sufficiently stable at high temperatures to exist alone.

THE additions to the Zoological Society's Gardens during the past week include a Chimpanzee (*Anthropopithecus troglodytes* δ) from West Africa, presented by Major Al. McDonnell Moore; a Duyker Bok (*Cephalophus mergens* δ) from South Africa, presented by Mr. A. Barsdorf; five West Indian Agoutis (*Dasyprocta antillensis*) from Jamaica, presented by the Board of Governors of the Institute of Jamaica; a Spotted Cavy (*Cœlogenys paca*) from Guiana, presented by Mr. R. Kirk; two Slow Loris (*Nycticebus tardigradus*), a Javan Fish-Owl (*Ketupa javanensis*) from Java, presented by Mr. R. Dixon; an Orange-cheeked Waxbill (*Estrelda melpoda*), a Zebra Waxbill (*Estrelda subflava*) from West Africa, a Nutmeg Finch (*Munia punctularia*) from India, presented by Mrs. Harris; a Chattering Lory (*Lorius garrulus*) from Moluccas, presented by Miss Alice Dundas; a Common Viper (*Vipera berus*), British, presented by Mr. W. H. B. Pain; four Grey Parrots (*Psittacus erithacus*) from East Africa, deposited; a Thar (*Capra jemlaica*), born in the Gardens.

OUR ASTRONOMICAL COLUMN.

LUMINOUS OUTBURST OBSERVED ON THE SUN.—*Comptes rendus* for June 22 contains the information that on June 17, at 10h. 16m. Paris mean time, M. Trouvelot observed a luminous outburst on the sun, apparently of the same character as that witnessed by Carrington and Hodgson in 1859 (*Monthly Notices R.A.S.*, vol. xx. pp. 13–16). A luminous spot subtending an angle of 3° appeared near the western limb of the sun (position-angle 281°). It had not the characteristic white colour of faculæ, but was yellowish, and strikingly resembled the light emitted by incandescent lamps shortly before they reach their maximum brilliancy. M. Trouvelot's first impression was that an opening at the eye-piece allowed a ubiquitous sunbeam to fall upon the screen upon which the sun's image was being projected, but an examination proved that the phenomenon was truly solar. In fact, shortly after the time of the first observation, a similar brilliant object subtending an angle of about 5′ or 6′ appeared slightly to the north of the first, its position-angle being about 289°. By means of spectroscopic observations it was found that the first object consisted of a central eruption from which a species of incandescent volcanic bombs were thrown to heights of 2′ or 3′ above the chromosphere, where they rested as if suspended, and appeared as dazzling globes on the red background on which they were projected. A few minutes later the sparkling balls were replaced by numerous brilliant filaments or jets, which at 10h. 24m. were shot out to a height of 5′ 24″. In spite of the vivid light of this prominence only a few lines in the spectrum were seen to be reversed. In addition to the lines C, D_3, F, and G, which were all extremely bright, the line at λ 6676·8, the *b* group, and a line about λ 4394·8, were seen bright. The sodium lines, D_1 and D_2, showed no indication of reversal. Considerable displacements of the C line towards both ends of the spectrum were observed. On the following day at 9h. 30m. the eruption was still very apparent, but diminishing in activity, and at 2h. 45m. all signs of an eruptive prominence had disappeared. The striking character of the outburst led M. Trouvelot to suggest that it might be accompanied by a simultaneous terrestrial magnetic perturbation. This was not the case, however, for after examining the records obtained at Kew Observatory, Mr. Whipple writes that there was not the slightest magnetic disturbance on the dates when the eruption was observed.

LORD HARTINGTON ON TECHNICAL EDUCATION.

THE fourth annual meeting of the National Association for the Promotion of Technical and Secondary Education took place on Friday last at 14 Dean's Yard, Westminster. Lord Hartington, President of the Association, occupied the chair. He said:—

In opening the proceedings it will be, fortunately, unnecessary for me to trouble you with more than a very few brief observations. It has not been considered necessary to make any

Digitized by Google

attempts to obtain a very large attendance to-day, or to meet in any place where we could have a meeting on the scale of others which we have had on this subject in previous years, not but that we have arrived at a very important epoch in the development of the objects for which this Association was founded four or five years ago. It may, perhaps, be desirable for me, in the first place, to call your attention and the attention of the public to the special objects for which this Association has been founded, as I think there is in some quarters some misapprehension as to the practical nature of the objects which we have in view. As is stated in the report, its object has not been to interfere with the teaching of trades in workshops, or with the industrial and commercial training in the manufactory and in the warehouse. It desires, first of all, to develop increased general dexterity of hand and eye among the young, which may be especially useful to those who have to earn their own livelihood, and at the same time improve rather than hinder their general education; secondly, to bring about more widespread and thorough knowledge of those principles of art and science which underlie much of the industrial work of the nation; and, thirdly, to encourage better secondary instruction generally, which will include more effective teaching of foreign languages and science, for those who have to guide our commercial relations abroad and to develop our interests at home. Now, those are the objects to carry out which this Association was founded. At the time when it was first originated, these objects were very little recognized in any quarter. They were not recognized as in any degree the duties of the State, except to a very limited extent, so far as the operations of the Science and Art Department were concerned. But, useful and valuable as has been the teaching carried on under the guidance and direction of the Science and Art Department up to a very short time ago, I think it may be said that scarcely any attempt had been made to give to that teaching a practical application, or to apply its instruction to the advancement and improvement of the industries of the country. Well, the absence of any State recognition was not to any large extent supplied at that time by private efforts. It is quite true that a few manufacturers in different parts of the country had set the very useful example of establishing, in connection with their works, some technical and scientific teaching. There were also a few institutions, such as the well-known Polytechnic Institution here, others in the City and in various other parts of the country, which were making attempts to give instruction with the objects which I have just enumerated, but those efforts were rather of a philanthropic than of a practical character, and they had not four or five years ago attained a very large or extensive development. Well, we may look back now at those years as years of very great and very satisfactory progress. I will not say all that has been done has been done in consequence of the exertions of this Association. Certainly these objects have been greatly advanced since the foundation of the Association, and, we flatter ourselves, to a certain extent in consequence of the efforts of the Association. But whether the progress that has been made has been in consequence of, or independent of, any exertion of ours, it is equally a matter of congratulation that progress has been made. In the first place, those objects to which I have already referred have been recognized by Parliament as proper objects to receive assistance, by means of public funds, in the shape of the application to them of the rates. By the Technical Instruction Act, which was passed in 1889, mainly at the instance of some active Parliamentary representatives of this Association, that principle was for the first time admitted; but a very much greater step was taken in the next year, 1890, when, under the Local Taxation Act, a sum very nearly approaching £750,000 for England and Wales was placed at the disposal of local authorities, mainly for the objects which this Association has in view. It is quite true that the application of that sum was to a large extent optional. It would have been in the power of local authorities in whose hands it was placed to apply it in aid of the rates or to other purposes, but the efforts of the Association were directed, as I think I shall be able to show you, with very great success, in order to secure the appropriation of these large funds to the purposes of practical technical instruction. You will recollect that in the winter of last year—I think in December—an important conference was held under the direction of the Executive Committee of this Association at the rooms of the Society of Arts, in which members representing County Councils in various parts of the country entered into conference and discussion with the Executive Committee of this Association. Information was given as to what had already been done by certain County Councils which had taken the lead, and suggestions were made as to the manner in which other Councils could most usefully follow their steps and devote these sums to the purposes for which we believe they were intended by Parliament. The results which have already been accomplished are recorded in the report of this Association, which will be immediately circulated. Of County Councils in England, excluding Monmouthshire, 37 have already decided to give the whole of this grant for the purposes of technical instruction; 8 have decided to give a part of this grant for the same purposes, and 2 only have decided to apply the whole of it in aid of the rates. In Wales and Monmouthshire 11 County Councils have given the whole to education, and 2 have given a part to the same purpose. Of the county boroughs in England, 33 have devoted the whole of the funds to educational purposes, and 3 have devoted a part to the same objects. In Wales 2 county boroughs have devoted the whole of the fund to education, and none to any other purposes. With regard to 23 county boroughs, either we have not sufficient information, or they have not yet arrived at a conclusion upon the subject. Well, that appears to us to be an extremely encouraging result so far as it has gone. The exertions of the Executive Committee have not, however, been entirely confined to securing this appropriation of the funds placed at the disposal of the Councils by Parliament. The same gentlemen who have taken the lead in the matter from the beginning—I refer chiefly to my friend Sir Henry Roscoe, Mr. Acland, Mr. Hobhouse, and others—have obtained from Parliament additional legislation considerably extending and developing the principle which for the first time received the assent of Parliament in 1889. I think it is hardly necessary that I should give further information as to the effect of the amending Act of this session. I prefer to leave the gentlemen I have named to give that explanation. But I desire, however, to point out that the work of this Association, which has been so successfully begun, has not by any means yet ended. The application of these grants in the various localities is, of course, a work of great variety and of the utmost importance. Fortunately, I think, the State has not undertaken, except under very wide conditions, to exercise any supervision over the application of these funds. In a country possessing industries of so extremely varied a character as ours, it would have been almost impossible, and I think certainly would have been most undesirable, that any cut-and dried system should be adopted by which one identical, application of public money to purposes of technical instruction should be adopted all over the country. The application of these funds must vary very greatly in agricultural districts, and in agricultural districts themselves as between arable and dairy or cheesemaking districts. It must vary in those districts which are chiefly devoted to cotton and woollen industries, and those which are chiefly employed in the coal-mining, metal, or chemical trades; and in almost every different county of England a different application of those resources would have been required. I think very wide discretion has been very wisely left by Parliament to the local authorities themselves, which are in this instance County Councils or county borough councils. And these Councils have again adopted the wise course of appointing committees to prepare schemes for the approval of the Councils for the application of these grants. The work was, of course, very new to a great many who had to take it up, and this Association has been able, we think, to give valuable assistance to them, both by affording information and giving advice, and, above all, by providing the means of communication between those who are interesting themselves in this work in various parts of the country, to enable them to know what other authorities were doing, what difficulties were found, what means had been found of surmounting those difficulties, and of generally taking counsel and acting together in co-operation. Now, the subject of agricultural education, which up to a very short time ago had been almost entirely neglected, has been by many County Councils vigorously taken up. Courses of instruction in elementary science applying to agricultural pursuits have been instituted, and also instruction of a still more practical character, in the shape of travelling dairies and other instruction of the same kind, has been given in many places. I am glad to say that the two great Universities of Oxford and Cambridge have also turned their attention to this important subject, and both of them are preparing to take steps by which the teachers who will be so much required in order to give effect to

Digitized by Google

the desire of the County Councils to improve the agricultural education of their districts will be provided. I am glad to say also that the important subject of the technical education of girls as well as boys is receiving almost universal attention from County Councils. Suggestions have been made by this Association, which have in most cases received attention, to provide not only for the instruction of the boys, but also of the girls, in such subjects as cookery, laundry-work, and dairy management. In all these matters the Association has been able to give some assistance, and we believe that there remains a great deal still in which they will be able to afford the same nature and description of assistance. I need not say, ladies and gentlemen, that for a very considerable time the work which is likely to be thrown upon this Association will be work which cannot be conducted without considerable financial resources. The income of the Association is not a very large one. We have made an appeal to many of those who throughout the country have interested themselves in this work in connection with County Councils, and we have received very liberal assistance. I think, however, the time has come when we may hope that the efforts which have been made will be to a certain extent, still more than they have hitherto been, supplemented by the assistance of gentlemen connected with the great manufacturing, mining, and commercial industries of the country, who are likely, I think, to derive at least as much benefit from the operations of this Association, and from the development which it has aided in giving technical instruction throughout the country, as the agricultural industry has already received. Ladies and gentlemen, I must apologize to you for the imperfect character of these observations, which I have been obliged to condense as much as possible, as my time, and I dare say yours, is extremely limited. I only hope that any omissions which I have made will be supplied by my friends who are on each side of me.

Sir H. Roscoe, M.P., presented the report of the work of the Association during the past year. He said that there was no doubt that during the year a very great expansion of the work of the Association had been seen under both the Acts of Parliament to which reference had been made by the Chairman. The spread of technical education throughout the country had been most remarkable. From what had already been said by Lord Hartington, it would be concluded that practically the whole of England had devoted the whole of the money to technical instruction. The effects of this could scarcely be over-estimated. The only two places where the money had been devoted to the relief of the rates were, he regretted to say, London and Middlesex. But it should be borne in mind that what had been already accomplished was nothing to what remained to be done. The County Councils were as yet only breaking the ground. Their efforts were merely tentative. They had, as it were, to work out their own salvation in this matter of education, and there was certain to be at no great distance of time an Intermediate Education Act for England. Referring to the Act of 1891, he said that it was important and valuable because it enabled a County Council to go out of its own district if it thought necessary to promote technical education. Under that Act, for instance, the three Ridings of Yorkshire had been able to vote money to assist the Yorkshire College in its scheme for the improvement of agricultural education. Many of the County Councils had already appointed organizing secretaries, and it was on these that the main part of the work would fall. To them they had to look for the special organization of each particular district, and the importance of their work could scarcely be overrated. Then in the county boroughs the work was being got into shape. In Sheffield a sum of £8495 had been appropriated towards assisting institutions giving technical and secondary education. In the same way in Manchester £10,200 had been devoted to a like purpose. Agricultural education was making rapid progress, and already in Yorkshire, Durham, and Wales there was the nucleus of high class agricultural colleges. After referring to the necessity of some part of the money being devoted to the technical instruction of girls, he concluded by expressing the hope that the Association would be placed in a position by an increase of its resources to carry on actively a work that was daily becoming more important and more costly.

On the motion of Mr. H. Hobhouse, M.P., seconded by Lord Thring, the report was unanimously adopted.

Lord Hartington at this point left the chair, which was taken by Sir Bernhard Samuelson.

Lord Monteagle moved the reappointment of the vice-president, executive committee, and officers of the Association, the name of Mr. Bryce, M.P., being substituted for that of the late Earl Granville. Dr. Gladstone seconded, and Mr. Snape supported, the motion, which was carried unanimously.

Mr. Bryce, M.P., proposed the following resolution :—

"That this Association heartily congratulates the County Councils of England and Wales on the great progress they have made during the past year in the promotion of education in their districts, and earnestly trusts that they will continue to work until the country is provided with an organized system of secondary and technical education."

Miss Hadland seconded the resolution, which was agreed to.

Sir John Lubbock, M.P., proposed, and Mr. Rathbone, M.P., seconded, a vote of thanks to the Chairman, and this having been heartily accorded was acknowledged by Sir Bernhard Samuelson.

The proceedings then terminated.

SCIENTIFIC SERIALS.

IN the *Journal of Botany* for May, Prof. R. J. Harvey-Gibson has an interesting article, illustrated, on the histology of *Polysiphonia fastigiata*. In the June number, Mr. A. W. Bennett contributes a short paper on sexuality among the Conjugatæ. These numbers also contain continuations of Mr. E. G. Baker's synopsis of the genera and species of Malveæ, and of the Rev. H. G. Jameson's useful key to the genera and species of British mosses.

THE papers in the *Botanical Gazette* for April and May are concerned almost exclusively with American botany. Mr. D. M. Mottier has an interesting note on the apical growth of Hepaticæ, which bears such a striking resemblance to that of the prothallium of ferns.

THE number of the *Nuovo Giornale Botanico Italiano* for April is chiefly occupied by papers of special interest to Italian botanists, and by the Bulletin of the Italian Botanical Society. Among the articles coming under the latter head is one by Sig. Baccarini on the secretory system of the Papilionaceæ, and one by Sig. Pichi containing an account of experiments on the parasitism of *Peronospora* on the vine.

THE *Botanical Magazine* of Tokyo still contains occasional articles in the English language. Those in the numbers most recently received, for March and April, relate to the native plants of Japan.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, June 11.—"A Study of the Planté Lead—Sulphuric Acid—Lead Peroxide Cell, from a Chemical Standpoint. Part I." By G. H. Robertson. Communicated by Prof. Armstrong, F.R.S.

The investigation, the results of which are recorded in this paper, was instituted about a year ago at the Central Institution, at Dr. Armstrong's suggestion, as McLeod's observations on the electrolysis of sulphuric acid solutions led to the supposition that the changes occurring in the acid were probably less simple than was commonly supposed. This supposition was verified.

The first section of the paper deals with the nature of the lead salt formed during discharge. Experiments made on various samples of red lead of different percentage composition showed that, as with nitric, so with sulphuric acid, it behaved like a mixture of peroxide and monoxide, the sulphate formed always corresponding to the monoxide originally present.

As analysis alone can give no proof of the existence of a definite homogeneous sulphate corresponding to red lead: evidence must be obtained that the product differs in some of its properties from a mixture. It was to be expected that the E.M.F. of an oxysulphate would differ from a corresponding mixture of sulphate and peroxide, and have some definite value, but experiments made with mixtures of sulphate and peroxide in different proportions, and with the product obtained by treating red lead with dilute sulphuric acid, showed that there was a difference of degree only between the red lead pastes and the mixtures.

With regard to Frankland's observations respecting the

Digitized by Google

colour of the product formed on the peroxide plate during discharge, and the reducibility of the sulphate, the author points out that the colour is due to the incomplete reduction of the peroxide; and that careful examination of the plugs from a discharged cell shows that the base consists of practically unaltered peroxide of lead, and that the surface, which is rich in $PbSO_4$, is really a mass of partially reduced granules of peroxide of lead which are coated with sulphate.

Also, though pure lead sulphate is very difficult to reduce, it is well known that mixtures of lead sulphate and peroxide of lead, or other conducting substances, are reduced with comparative ease, and that it is very intimate mixtures of this nature which have to be dealt with as a rule in charging a cell.

In conclusion, the author points out—

That neither chemical nor electrical tests give any ground for supposing that any other sulphate than the ordinary white $PbSO_4$ is concerned in the interactions occurring in the cell;

That were the sudden lowering of the E.M.F. caused by a change in the nature of the chemical compounds formed on the plates, it is very difficult to account for the very rapid recovery of the E.M.F. exhibited by an apparently discharged cell.

In the second section the electrolyte is dealt with, and, after referring to the work of Berthelot, Richarz, Schöne, Traube, and others on the electrolysis of sulphuric acid solutions, the author describes experiments made to test the effect of the addition of sodium sulphate to the electrolyte, as recommended by Mr. Barbour Starkey, as it seemed probable it had a catalytic action on the "peroxides" always found in electrolyzed acid of the strength used in batteries.

Mr. Preece most kindly aided the investigation by allowing experiments to be carried out at the General Post Office, where one-half of the secondary cells contain 1 per cent. of sodium sulphate, and the other half ordinary dilute acid, sp. gr. 1180. It was found that the addition of sodium sulphate in about the proportion of 1 per cent. to freshly electrolyzed acid, or during electrolysis, always produced a diminution in the total quantity of "active oxygen," and brought the amount present in the plain cells down almost exactly to that found in the sodium sulphate cells.

Determinations were made of the amounts of "active oxygen" present as persulphuric acid and hydrogen dioxide respectively; and it was established that acid taken from the cell reduced peroxide of lead. The presence of hydrogen dioxide being thus established both directly and indirectly, its effect on the E.M.F. of a cell was tested. It was found that, while its addition to the acid in the case of a lead lead-peroxide couple in dilute sulphuric acid produced an annulment, or reversal, of the E.M.F., the introduction of hydrogen dioxide into the body of the peroxide paste produced an increase in the E.M.F. in the case of a platinum lead-peroxide couple.

The Post Office records showed that, while the general character of the temperature and specific gravity changes occurring during charge and discharge were the same in both types of cell, there was less sulphating with the sodium sulphate electrolyte.

The cause of the pink colour of the acid, noticed by Mr. Crompton and others, was investigated, and found to be permanganic acid, formed probably from the manganese present in commercial lead.

In conclusion, the author points out—

That peroxides are found in appreciable quantities in the electrolyte during charge and discharge;

That their influence must not be neglected in considering the behaviour of the Planté cell;

And that it is to the electrolyte, rather than to the plates, that attention must be directed if any considerable improvement is to be effected.

"Part II.—A Discussion of the Chemical Changes occurring in the Cell." By H. E. Armstrong, F.R.S., and G. H. Robertson.

The authors arrive in this paper at the following conclusions:—

(1) That the cooling observed in the Planté cell can only be explained as resulting from the dissociation of the dilute sulphuric acid; and as the values given by Messrs. Ayrton, Lamb, Smith, and Woods are in practical agreement with those calculated on the assumption that the acid used is sulphuric acid itself, H_2SO_4, that in all probability such acid, and not the dilute acid contained in the cell, is operative throughout.

(2) That the observed loss in efficiency cannot be due to temperature changes, as these arise through actions occurring out of circuit.

(3) That it is difficult, from a comparison of calculated with observed values of the E.M.F., to arrive at any final conclusion as to the exact nature of the changes which take place in the cell. On the assumption that sulphating occurs at both plates in circuit, and under the influence of H_2SO_4, the calculated value is considerably too high; while, if sulphating occur only at the lead plate, the value calculated is far too low.

(4) That a counter E.M.F. of about 0·5 volt would account for the observed departure from the highest calculated value. As peroxides are always present in the electrolyte, it is conceivable that such a counter E.M.F. may exist; moreover, there is also the possible influence of the lead support to be considered.

(5) That the observed loss of efficiency is to be attributed to the formation of peroxides in the electrolyte, and to the excessive sulphating occurring chiefly at the peroxide plate in the local circuit existing between the support and the paste.

June 18.—"Comparison of Simultaneous Magnetic Disturbances at several Observatories, and Determination of the Value of the Gaussian Coefficients for those Observatories." By Prof. W. Grylls Adams, D.Sc., F.R.S., Professor of Natural Philosophy in King's College, London.

After drawing attention to previous investigations on this subject, and pointing out the importance of adopting the same scale values for similar instruments at different Observatories, especially at new Observatories which have been recently established, the discussion of special magnetic disturbances is undertaken, especially the disturbances of a great magnetic storm which occurred on June 24 and 25, 1885, for which photographic records have been obtained from 17 different Observatories: 11 in Europe, 1 in Canada, 1 in India, 1 in China, 1 in Java, 1 at Mauritius, and 1 at Melbourne.

The records are discussed and compared, tables are formed of the simultaneous disturbances, and the traces are reduced to Greenwich mean time and brought together on the same plates arranged on the same time-scale. Plates I. and II. show the remarkable agreement between the disturbances at the different Observatories, and the tables show that the amount of disturbance, especially of horizontal magnetic force, is nearly the same at widely distant stations.

An attempt has also been made to apply the Gaussian analysis to sudden magnetic disturbances, and, with a view to their application in future work, the values of the Gaussian coefficients have been obtained for 20 different Observatories, and the numerical equations formed for the elements of magnetic force in three directions mutually at right angles, and also the equation for the magnetic potential in terms of the Gaussian constants to the fourth order.

The tables give the numerical values to be multiplied by the 24 Gaussian constants to give the values of the forces X, Y, and Z in the geographical meridian towards the north, perpendicular to the meridian towards the west, and towards the earth's centre respectively. The equations are also formed and the values obtained in terms of the 24 Gaussian constants for X_2, Y_2, and Z_2; X_2 being the horizontal force in the magnetic meridian, Y_2 the horizontal force perpendicular to the magnetic meridian, and Z_2 the vertical force. If then X_2, Y_2, and Z_2 be the observed values of any simultaneous disturbances, they may be at once substituted in the equations, the equations giving the 24 Gaussian constants may be solved, and the corresponding change of magnetic potential may be determined.

Physical Society, June 12, 1891.—Prof. W. E. Ayrton, F.R.S., President, in the chair.—Prof. W. G. Adams took the chair whilst Prof. Ayrton read a paper on alternate current and potential difference analogies in the methods of measuring power, by himself and Dr. Sumpner. In a paper read before the Society in March last, the authors pointed out that, for every method of measuring power in which readings of volts and amperes were taken, other methods in which amperes were read instead of volts, and volts instead of amperes, could be devised. More recently, Dr. Fleming had, by a transformation of a formula given by the authors in a communication made to the Royal Society on the measurement of power by three voltmeters, given the analogue in which three ammeters were employed. The two arrangements are represented in Figs. 1 and 2, whilst Fig. 3 shows a modification of Dr. Fleming's method (Fig. 2), in which the current in the non-inductive resistance r is

Digitized by Google

measured by the aid of a voltmeter V across its terminals. This obviates the necessity of putting an electro-magnetic instrument

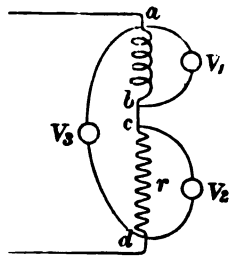

FIG. 1.

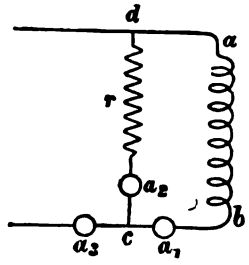

FIG. 2.

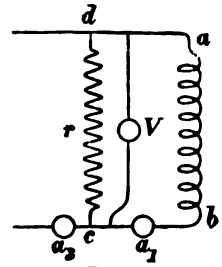

FIG. 3.

in what should be a non-inductive circuit. The formula for the mean watts spent in the circuit *ab*, Figs. 1 and 2, are respectively—

$$W = \frac{1}{2r}\left(V_3^2 - V_1^2 - V_2^2\right), \text{ and } W = \frac{r}{2}\left(A_2^2 - A_1^2 - A_3^2\right).$$

Mr. Blakesley's method of measuring power by a split-dynamometer was shown to be analogous to the original electrometer method in which the difference of two readings was proportional to the power, and Blondlot and Currie's double electrometer method was shown to be the analogue of the ordinary wattmeter. The wattmeter was defective in the fact that a solenoidal coil was inserted in a nominally non-inductive circuit. The error thus introduced is, as was shown by one of the authors some years ago, expressed by the formula—

$$\frac{\text{Apparent watts}}{\text{True watts}} = \frac{1 + \tan\theta \,.\, \tan\phi}{1 + \tan^2\phi},$$

where θ is the phase angle between the current and E.M.F. in the circuit in which the power is to be measured, and ϕ the phase angle for the approximately non-inductive circuit. It is now proved that the same formula expresses the error in any of the methods where resistances not wholly non-inductive are used. As is well known, Mr. Blakesley has applied his split-dynamometer to the measurement of phase differences between two currents; and an analogous method of finding the phase difference between two potential differences is described in the paper. In this method a high resistance split-dynamometer such as suggested by Mr. Rimington for measuring power is employed. Blondlot and Currie's double electrometer could also be used for the same purpose. Numerous diagrams illustrating the various analogies accompany the paper. Prof. S. P. Thompson inquired whether hot-wire voltmeters could be employed to measure the various potential differences, without introducing error. In reply, Prof. Ayrton said that, although no great error was introduced by the self-induction of these instruments, yet the fact that they required considerable current was a disadvantage, and as these currents were not always in the same phase as those in other circuits, troublesome corrections were sometimes necessary. Electrostatic instruments were preferable. Prof. Adams said he was glad to hear that the inductance of Cardew voltmeters introduced no serious error, for they were very convenient instruments to use.—Prof. O. Lodge, F.R.S., exhibited and described a clock for pointing out the direction of the earth's orbital motion in the ether. After mentioning the various motions to which a point on the earth's surface is subjected, he pointed out that the orbital motion was the largest component, and its direction at any instant not easy to conceive. An apparatus for pointing out this direction was therefore convenient when dealing with problems requiring a knowledge of the motion of a point through the ether. In one of two clocks shown, one spindle representing the earth's polar axis and another the axis of the ecliptic were inclined at an angle of 23½°, and coupled by a Hooke's joint. The latter axis was capable of rotating round the former. At its upper end the ecliptic axis carried a tube and a pointer, both being perpendicular to the axis and to each other. The clock keeping solar time rotated both axes, and when properly set the tube pointed in the direction of the sun, and the pointer therefore indicated the direction of the earth's orbital motion.—Some experiments with Leyden jars were then shown by Dr. Lodge. The first one was with resonant jars, in which the discharge of one jar precipitated the overflow of another, when the lengths of the jar circuits were properly adjusted or tuned. The latter jar was entirely disconnected from the former, and was influenced merely by electro-magnetic waves emanating from the discharging circuit. Lengthening or shortening either circuit prevented the overflow. Correct tuning was, he said, of great importance in these experiments, for a dozen or more oscillations occurred before the discharge ceased. The effect could be shown over considerable distances. In connection with this subject Mr. Blakesley had called his attention to an observation made by Priestley many years ago, who noticed that, when several jars were being charged from the same prime conductor, if one of them discharged the others would sometimes also discharge, although they were not fully charged. This he (Dr. Lodge) thought might be due to the same kind of influence which he had just shown to exist. The word *resonance*, he said, was often misunderstood by supposing it always had reference to sound, and as a substitute he thought that *symphoning* or *symphonic* might be allowable. The next experiment was to show that wires might be tuned to respond to the oscillation of a jar discharge just as a string could be tuned to respond to a tuning-fork. A thin stretched wire was connected to the knob of a jar and another parallel one to its outer coating, and by varying the length of an independent discharging circuit, a glow was caused to appear along the remote halves of the stretched wires at each discharge. Each of the wires thus acted like a stopped organ-pipe, the remote ends being the nodes at which the variations of pressure were greatest. By using long wires he had observed a glow on portions of them with the intermediate parts dark; this corresponded with the first harmonic, and by measuring the distance between two nodes he had determined the wave-length of the oscillations. The length so found did not agree very closely with the calculated length, and the discrepancy he thought due to the specific inductive capacity of the glass not being the same for such rapidly alternating pressures as for steady ones. He also showed that the electric pulses passing along a wire could be caused (by tuning) to react on the jar to which it was connected, and cause it to overflow even when the distance from the outside to the inside coating was about 8 inches. During this experiment he pointed out that the noise of the spark was greatly reduced by increasing the length of the discharging circuit. The same fact was also illustrated by causing two jars to discharge into each other, spark gaps being put both between their inner and outer coatings so as to obtain "A" sparks and "B" sparks. By putting on a long "alternative path" as a shunt to the B spark gap and increasing that gap, the noise of the A spark was greatly reduced. He had reason to believe that the B spark was a quarter phase behind the A spark, but the experimental proof had not been completed. He next described some experiments on the screening of electro-magnetic radiation, in which a Hertz resonator was surrounded by different materials. He had found no trace of opacity in insulators, but the thinnest film of metal procurable completely screened the resonator. Cardboard rubbed with plumbago also acted like a nearly perfect screen. In connection with resonators, he exhibited what he called a *graduated electric eye* or an *electric harp*—made by his assistant, Mr. Robinson—in which strips of tin foil of different lengths are attached to a glass plate, and have spark gaps at each end which separate them from other pieces of foil. One or other of the strips would respond according to the frequency of the electro-magnetic radiation falling upon it. Mr. Blakesley asked whether the pitch of the resonant jars altered when the distance between their circuits was varied, for according to theory the mutual induction should diminish the self-induction, and cause the oscillations to be more rapid. If this occurred, the method might be used for getting rapid oscillations. He also inquired whether the glow would appear in the same position on the two stretched wires if their

Digitized by Google

ends were joined. Dr. Sumpner wished to know how the resistances, inductances, and capacities of the circuits and jars were determined, and whether any evidence of irregular distribution of the charges on the tin-foil had been noted. With reference to the overflowing of a jar caused by using a certain length of discharging circuit, he asked whether the overflow did not prove the existence of a higher potential than that which originally existed between the coatings of the jar, and, if so, where did the excess energy come from? Dr. Thompson asked if it would be possible to make a wire circuit analogous to an open organ-pipe by putting sheets of metal on the ends of the wires. Dr. Lodge, in reply, said Mr. Blakesley's suggestion was an important one, but he had not observed that any change in the adjustment was necessitated by varying the distance between the resonating circuits. Neither had he noticed any glow on wires joined to form a single loop, but this might be possible if the wires were long enough to give harmonics. In answer to Dr. Sumpner he said that the capacities were difficult to determine, for with such rapid oscillations the coatings were virtually enlarged. Lord Rayleigh had shown how to calculate the inductances, and the resistances he had practically measured by his alternative path experiments. The overflow of jars he thought was caused by the charges in some way concentrating on the edges of the foil, thus causing a kind of flood tide, at which the overflow occurred. The President asked Dr. Lodge what his views were as to the cause of the opacity of ebonite to light. Was it due to a selective absorption which cut off only the rays to which the eye was sensitive, or was the ordinary explanation, that it contained impurities which were conducting, and hence acted as screens, likely to be correct? Another possible explanation was that the motion of the ether particles may be in three dimensions, and light be due to the projection of this motion on a plane perpendicular to the ray, whilst electromagnetic induction might be due to the other component. Dr. Lodge said he believed that ebonite was not opaque because of conducting particles being present, and was inclined to think that it acted more like ground glass, in which the opacity was due to internal reflections. Such a substance would only be opaque to vibrations whose wave-lengths were comparable with the size of the particles.—A note on the construction of non-inductive resistances, by Prof. W. E. Ayrton, F.R.S., and Mr. T. Mather, was postponed until next meeting.

Zoological Society, June 16.—Dr. St. George Mivart, F.R.S., Vice-President, in the chair.—Mr. H. A. Bryden exhibited an abnormal pair of horns of a cow Eland obtained in the North Kalahari, and made remarks on the structure of the feet of the Lechée Antelope.—Mr. Howard Saunders exhibited and made remarks on a nearly white skin of a Tiger obtained in Northern India by Major D. Robinson.—Mr. Saunders also exhibited specimens of the eggs of a Gull (*Larus maculipennis*) and of a Tern (*Sterna trudeaui*) from Argentina.—Mr. Sclater read an extract from a letter received from Dr. Bolau, C.M.Z.S., describing two Sea-Eagles living in the Zoological Garden, Hamburg, and considered to be referable to Steller's Sea-Eagle (*Haliaëtus pelagicus*). One of these, received from Corea, Mr. Sclater pointed out, probably belonged to the species described in the Society's Proceedings by Taczanowski as *Haliaëtus branickii*.—Dr. R. Bowdler Sharpe gave a short account of the proceedings of the International Ornithological Congress recently held at Budapest, in which he had taken part.—Mr. G. A. Boulenger read a paper entitled "A Contribution to our Knowledge of the Races of *Rana esculenta* and their Geographical Distribution." Mr. Boulenger proposed to recognize four forms of this widely-spread species of Frog, and pointed out the characters upon which these races were based and the areas which they occupy.—Mr. Oldfield Thomas read some notes on various species of Ungulates, which he had made during a recent examination of the specimens of this group of Mammals in the British Museum.—Mr. Edgar A. Smith gave an account of a large collection of Marine Shells from Aden. To this were added some remarks upon the relationship of the Molluscan Fauna of the Red Sea with that of the Mediterranean.—A second communication from Mr. Smith contained descriptions of some new species of Shells, based on examples obtained during the *Challenger* Expedition.—Mr. H. A. Bryden read some notes on the present distribution of the Giraffe south of the Zambesi, and made some remarks on the best means of procuring living specimens of this animal for European collections.—A communication was read from Messrs. Mole and Urich containing notes of some of the Reptiles of Trinidad, of which they had transmitted living examples to the Society's Menagerie.—Mr. F. E. Beddard read some additional notes upon the anatomy of *Hapalemur griseus*, made during a recent examination of two specimens of this Lemur.—Mr. E. B. Poulton gave an account of an interesting example of protective mimicry discovered by Mr. W. L. Sclater in British Guiana. This was an immature form of an unknown species of Homopterous insect of the family Membracidæ, which mimics the Cooshie Ant (*Œcodoma cephalotes*).—This meeting closes the present session. The next session (1891-92) will begin in November next.

Royal Microscopical Society, June 17.—Dr. R. Braithwaite, President, in the chair.—The President said he regretted to announce the death of Prof. P. Martin Duncan, who as a past President of the Society, was well-known to the Fellows.—A negative of *Amphipleura pellucida*, produced with Zeiss's new $\frac{1}{5}$ of 1·6 N.A. and sunlight, by Mr. T. Comber, of Liverpool, was exhibited, and his letter was read suggesting that the want of sharpness was due to the employment of a projection eye-piece for a tube-length of 160 mm., whereas the objective was made for a tube-length of 180 mm. The illumination was axial with a Zeiss achromatic condenser of 1·2 N.A. Mr. Comber thought the resolution showed indications of so-called "beading," and he inferred that the ultimate resolution would be similar to that of *Amphipleura lindheimeri*. The mounting medium had a refractive index of 2·2, but was very unstable, granulations appearing in a very short time.—Mr. C. L. Curties exhibited Mr. Nelson's apparatus for obtaining monochromatic light. Mr. Mayall said the apparatus was so devised that the microscopist might employ any prism or photographic lens he possessed. If a prism was made specially, one of light crown-glass would probably answer better than the dense flint.—Mr. T. T. Johnson exhibited a new form of student's microscope which he had devised. Mr. Mayall said the special point was the application of a screw movement to raise and lower the substage, the screw being in the axis of the bearings of the substage and tailpiece; and the position of the actuating milled head, which projected slightly at the back of the stage, seemed to be most happily chosen.—Dr. J. E. Talmage, of Salt Lake City, Utah, U.S.A., a newly elected Fellow, having been introduced by the President, read a note on the occurrence of life in the Great Salt Lake, and exhibited some specimens of *Artemia fertilis* from the lake.—Prof. Bell said a paper was read at the February meeting, in which Dr. Benham described a new earthworm under the name of *Eminia equatorialis*. The name *Eminia* having been already given to a bird by Dr. Hartlaub, Dr. Benham proposed to re-name the earthworm *Eminodrilus*.—A letter from Dr. Henri Van Heurck was read, replying to the criticisms of his microscope delivered at the previous meeting. A discussion followed, in which Mr. Mayall, Dr. Dallinger, and Mr. Watson joined.—Mr. T. D. Aldous exhibited the eggs of a water-snail which were attacked by a parasite which seemed to be destroying the gelatinous matter to get at the eggs.

Royal Meteorological Society, June 17.—Mr. Baldwin Latham, President, in the chair.—Mr. A. J. Hands gave an account of a curious case of damage by lightning to a church at Needwood, Staffordshire, on April 5, 1891. The church was provided with a lightning-conductor, but Mr. Hands thinks that when the lightning struck the conductor, a spark passed from it to some metal which was close to it, and so caused damage to the building.—Mr. W. Ellis read a paper on the mean temperature of the air at the Royal Observatory, Greenwich, as deduced from the photographic records for the forty years from 1849 to 1888, and also gave some account of the way in which, at different times, Greenwich mean temperatures have been formed.—Mr. Ellis also read a paper on the comparison of thermometrical observations made in a Stevenson screen with corresponding observations made on the revolving stand at the Royal Observatory, Greenwich. From this it appears that the maximum temperature in the Stevenson screen is lower than that of the revolving stand, especially in summer, and the minimum temperature higher, whilst the readings of the dry and wet bulb thermometers on both the screen and the stand, as taken at stated hours, agree very closely together.—Mr. W. F. Stanley exhibited and described his phonometer, which is really a new form of chronograph, designed for the purpose of ascertaining the distance of a gun from observations of the flash and report of its discharge, by the difference of time that light and sound take in reaching the observer. The instrument can also be used for measuring the distance of lightning by timing the interval between the flash

Digitized by Google

and the report of the thunder.—A paper was also read by Mr. A. B. MacDowall, on some suggestions bearing on weather prediction.

Geological Society, June 24.—Sir Archibald Geikie, F.R.S., President, in the chair.—The following communications were read:—On wells in West Suffolk boulder-clay, by the Rev. Edwin Hill. It might be supposed that in a boulder-clay district water could only be obtained from above or from below the clay. But in the writer's neighbourhood the depths of the wells are extremely different, even within very short distances; and since the clay itself is impervious to water, he concludes that it must include within its mass pervious beds or seams of some different material which communicate with the surface. It would follow that this boulder-clay is not a uniform or a homogeneous mass. The visible sections are only those given, at hand by ditches, and at a considerable distance north and south by pits at Bury St. Edmunds and Sudbury. The appearances in these harmonize with that conclusion. Conclusion and appearances differ from what we should expect on the theory that this boulder-clay was the product of the attrition between an ice-sheet and its bed. The reading of this paper was followed by a discussion in which Prof. Prestwich, Dr. Evans, Mr. Clement Reid, Mr. Charlesworth, Mr. Topley, Mr. Goodchild, the President, and the author took part.—On the melaphyres of Caradoc, with notes on the associated felsites, by Frank Rutley.—Notes on the geology of the Tonga Islands, by J. J. Lister. (Communicated by J. E. Marr, F.R.S.)—On the Inverness earthquakes of November 15 to December 14, 1890, by C. Davison. (Communicated by Prof. Chas. Lapworth, F.R.S.) In this paper the author gives reasons for supposing that the Inverness earthquakes of last year were due to the subsidence of a great wedge of rock included between a main fault and a branch one; and he considers that there is little doubt that these recent earthquakes were the transitory records of changes that, by almost indefinite repetition in long past times, have resulted in the great Highland faults.—The next meeting of the Society will be held on Wednesday, November 11.

PARIS.

Academy of Sciences, June 29.—M. Duchartre in the chair.—On persulphates, by M. Berthelot. Some new facts are stated in proof of the existence of persulphuric acid not merely as an anhydride, S_2O_7, but also as a compound capable of forming distinct salts, similar as regards composition to permanganates, perchlorates, permolybdates, and pertungstates.—Experiments on the mechanical actions exercised on rocks by gas at high pressures and in rapid motion, by M. Daubrée. The author shows that volcanoes of the same group have approximately the same height, and points out that it is probable that each group is the result of internal action at one centre. These considerations are applied to old volcanic rocks, which often exhibit a marked tendency to equality of level. The experiments which throw light on the disturbances investigated were previously described.—Action of sodium alcoholates on camphor: new method of preparation of alkyl camphors, by M. A. Haller.—On a cryptogam parasite of locusts, by M. Charles Brongniart.—On surfaces possessing the symmetry of plane systems, by M. S. Mangeot.—On homogeneous finite deformations: energy of an isotropic body, by M. Marcel Brillouin.—On the biaxial character of compressed quartz, by M. F. Beaulard.—The photogenic efficiency of different sources of light, by M. A. Witz.—On an electro-magnetic bell, by MM. Guerre and Martin.—Contribution to the study of atmospheric electricity, by M. Ch. André. It is generally admitted that atmospheric electricity is subject to a diurnal variation. A discussion of the observations made by M. Mascart at Lyons since 1884 shows that electric potential varies in much the same manner as barometric pressure and relative humidity. In fact, curves showing the annual variations of relative humidity and electric potential have precisely the same form.—On the oxidation of azo-compounds, by M. Charles Lauth.—On the formation of the mesentery and the intestinal canal in the embryo of the fowl, by M. Dareste.—On the sting of *Heterodera Schachtii*, by M. Joannes Chatin.—On Cladosporiæ Entomophytæ, a new group of parasitic fungi of insects, by M. Alfred Giard.—Contribution to the study of the differentiation of the endoderm, by M. Pierre Lesage.—On the destruction of *Peronospora Schachtii* of the beetroot, by means of compounds of copper, by M. Aimé Girard.—Influence of muscular exercise on the excretion of urinary nitrogen, by M. Chibret.

BRUSSELS.

Royal Academy of Sciences, April 4.—M. F. Plateau in the chair.—On the characteristic property of the common surface of two liquids under their mutual affinity, Part iii., by M. G. Van der Mensbrugghe. The observations given in the first paper indicated that the common surface of two liquids which act upon one another is subjected to a force whose direction is away from the centre of curvature. In the present note the author gives some new facts which appear to render this *force d'extension* very manifest. When a drop of olive oil is put upon the surface of distilled water, it slowly breaks up into a lens-shaped drop on the water surface and a spherical drop which descends to the bottom of the containing vessel. It is shown that a slow diminution occurs of the tension of the surface common to the oil and water. This diminution apparently arises from a slow chemical action between the two liquids, and which, if sufficiently prolonged, is manifested by the formation of a thin pellicle separating them. Many such phenomena as these are stated and explained according to the new theory.—Fourth note on the structure of the equatorial bands of Jupiter, by M. F. Terby. The author remarks that he was the first to comment upon the structure of Jovian equatorial bands, and to make known the fact that it is observable in small instruments. In a recent publication Mr. Keeler has overlooked these observations, and rendered this rectification necessary.—On the number of invariant functions by M. Jacques Deruyts.—*A propos* the rotation of the planet Venus, by M. L. Niesten (see NATURE, June 18, p. 164).—Geometrical calculation of the distances of remarkable points of triangles, by M. Clément Thiry.

MACMILLAN & CO.'S NEW SCIENTIFIC BOOKS.

NEW VOLUMES OF MACMILLAN'S MANUALS FOR STUDENTS.

A NEW TEXT-BOOK OF CRYSTALLOGRAPHY.

Crown 8vo, Cloth, 6s.

ELEMENTS OF CRYSTALLOGRAPHY FOR STUDENTS OF CHEMISTRY, PHYSICS, AND MINERALOGY. By GEORGE HUNTINGDON WILLIAMS, Ph.D., Assistant Professor in the Johns Hopkins University. Crown 8vo.

**** *A concise and elementary statement of the general principles of Crystallography, not intended as a complete treatise, but to furnish so much information on the subject as may be of service to students of other but allied branches.*

NATURE:—"We feel assured that the simultaneous publication in this country and in America of so simple and at the same time so accurate a text-book of the subject as the work we are now considering will do much towards reviving and diffusing a taste for the study of crystallography. The student who masters the contents of this little book will undoubtedly have much more to learn before he is competent to deal with all the higher problems of crystallographic science; but, however far his researches may be carried in the future—and this is, perhaps, the very highest praise we can give to the book—he will certainly have little, if anything, to *un*learn."

Crown 8vo, Cloth, 10s. 6d.

LESSONS IN ELEMENTARY BIOLOGY. By T. JEFFREY PARKER, B.Sc., F.R.S., Professor of Biology in the University of Otago, Dunedin, New Zealand. Illustrated.

NEW EDITION, REVISED.

Crown 8vo, Cloth, 10s. 6d.

A COURSE OF PRACTICAL INSTRUCTION IN BOTANY. By F. O. BOWER, D.Sc., F.R.S., Regius Professor of Botany, Glasgow.

NATURE:—"Everyone perusing the volume must be impressed with the high standard of its educational value. Teacher and student in this country are alike to be congratulated upon its publication."

ACADEMY:—"The work is one which should be in the hands of every practical botanist."

SATURDAY REVIEW:—"The types are good, easily obtained, and thoroughly worked out. . . . There is no padding, the text is to the point, and it assumes the presence of the plant concerned and the instruments in hand. We regard the absence of illustrations and of descriptive padding as important preventives of cram, and it should be clearly borne in mind that laboratory teaching suffers especially by the opening up of royal roads."

NEW VOLUME OF SIR WILLIAM THOMSON'S POPULAR LECTURES.

Crown 8vo, Cloth, 7s. 6d.

PAPERS ON NAVIGATION. By Sir WILLIAM THOMSON, LL.D., P.R.S., F.R.S.E., &c., Professor of Natural Philosophy in the University of Glasgow, and Fellow of St. Peter's College, Cambridge. [*Popular Lectures and Addresses*, Vol. III.

**** *The papers on navigation treat of such subjects as pilotage, astronomical navigation, "dead reckoning" or "account," deep-sea surroundings. In the papers relating to the tides, besides the general facts, the subjects of gravitation, the influence of the Straits of Dover on the tides of the British Channel and the North Sea, the tides of the southern hemisphere and the Mediterranean, the sketch proposed plan of procedure in tidal observation and analysis and the equilibrium theory of the tides, are discussed and dealt with.*

NEW EDITION OF VOL. I.

New and Revised Edition, Crown 8vo, Cloth, 7s. 6d.

THE CONSTITUTION OF MATTER. By Sir WILLIAM THOMSON, LL.D., P.R.S. With Illustrations. [*Popular Lectures and Addresses*, Vol. I.

NEW MATHEMATICAL SCHOOL BOOKS.

18mo, Cloth, 1s.

RIDER PAPERS ON EUCLID. BOOKS I. AND II. Graduated and Arranged in Order of Difficulty, with an Introduction on Teaching Euclid. By RUPERT DEAKIN, M.A., Balliol College, Oxford, Head Master of King Edward's School, Stourbridge.

BOOKS I. AND II. SEPARATELY.

18mo, 1s.

THE ELEMENTS OF EUCLID. BOOKS I. AND II. By I. TODHUNTER, F.R.S.

Globe 8vo, Cloth, 2s. 6d.

THE TRIGONOMETRY OF ONE ANGLE. By the Rev. J. B. LOCK, M.A., Author of "Arithmetic for Schools," "Trigonometry," "Elementary Statics," "Dynamics for Beginners," &c.

Globe 8vo, Cloth, 2s. 6d.

ELEMENTARY LESSONS IN SOUND, LIGHT, AND HEAT. By D. E. JONES, B.Sc., Professor of Physics in University College, Wales, Aberystwith, Author of "Examples in Physics," &c. With Illustrations.

**** *It is hoped that this book will be found useful, not only in schools, but generally among candidates for the elementary stage of the Science and Art Department's Examination, or for London University Matriculation.*

Globe 8vo, Cloth, 2s. 6d.

THE PROGRESSIVE EUCLID. BOOKS I. AND II. With Notes, Exercises, and Deductions. Edited by A. T. RICHARDSON, M.A., Senior Mathematical Master at the Isle of Wight College; formerly Scholar of Hertford College, Oxford. Illustrated.

SCOTSMAN:—"A capital Euclid to begin on."

MACMILLAN AND CO., LONDON.

MESSRS. MACMILLAN & CO.'S NEW BOOKS.

SECOND EDITION, THOROUGHLY REVISED, OF MARSHALL'S PRINCIPLES OF ECONOMICS.

Just Ready, Vol. I., 8vo, 12*s.* 6*d.* net.

PRINCIPLES OF ECONOMICS.

By ALFRED MARSHALL, M.A., Professor of Political Economy in the University of Cambridge, Fellow of St. John's College, Cambridge, sometime Fellow of Balliol College, Oxford. 2 Vols.

*** A copy of the Second Edition will be supplied to any purchaser of the First Edition who forwards his copy of the first edition together with a remittance for 7s. to Macmillan and Co. before September 30, after which date this offer will be withdrawn.*

Some Press Notices of the First Edition.

TIMES:—"This great treatise on economic science bids fair to take for the present generation the place which Mill's work took for the generation of forty years ago. It is a contribution of capital importance to the higher literature of economic science. . . . What is still more characteristic of the work is its wide command and felicitous application of 'curious facts,' its searching analysis of the mechanisms of business of all kinds, and its masterly treatment of human action and motive in their bearing on economical problems."

OBSERVER:—"In a sense, Prof. Marshall's work is the most striking book of the season."

NATURE:—"The uniformities of action resulting from such measurable motives may be regarded as the laws of motion in what Jevons called the *mechanics of industry*—a science which Prof. Marshall has cultivated with more success than any of his predecessors, owing to an unexampled combination of antithetical powers, the comprehensive grasp of mathematical reasoning, and the careful handling in detail of the observed facts. . . . We should like to dwell upon the practical importance of these conceptions. But it is impossible here to analyze a work almost every page of which presents a new idea."

GLASGOW HERALD:—"It is serious and thorough in the last degree; there is not a vestige of slipshod reasoning in it, yet it is extremely readable, and the hardest-headed business man might find its suggestions of practical value."

MANCHESTER GUARDIAN:—"The author has contrived, with a success which has not been approached since the appearance of Mill's great work, to combine the accurate complexity of a technical treatise with the suggestive interest of a practical contribution to social science."

SCOTSMAN:—"There can be no question that it is the most important and valuable contribution to the general theory of political economy, whether in this country or abroad, since the publication of J. S. Mill's 'Principles.' But although the book is in many respects profoundly original, there is no affected straining after originality, or irritating and complacent exposure of the errors and defects of others."

ACADEMY:—"Advances the position of the science as it were by leaps and bounds."

POLITICAL SCIENCE QUARTERLY (Prof. J. P. CLARK):—"Adding its own special contribution to the general result of past and present thinking, it presents the science of economics as it stands to-day in a nearer approach to unity than has seemed to be possible."

ANNALS OF THE AMERICAN ACADEMY (Prof. J. H. GIDDINGS):—"It does for political economy in the last decade of the nineteenth century what Smith did in the last quarter of the eighteenth, and what Mill did after the discussion of two generations had apparently fixed the fundamental lines. It gathers and sifts the store of economic knowledge. It reconstructs the whole body of doctrine on broader grounds, and in that new spirit at once more liberal and more severely scientific, that has characterized every department of thought in these later years."

SATURDAY REVIEW:—"This book is, without doubt, among the most important contributions to political science made by English authors within recent times. . . . Mr. Marshall exhibits it as a true and living branch of politics, as the study not merely of the logical consequences of competition between wealth-seeking individuals, but of the wealth of nations in the fullest sense. . . . The result is that his book, without any sacrifice of scientific exactness, has a literary merit and a human interest which are exceedingly rare in works on the subject, and that the dangers of misapprehension and perversion are reduced to the lowest possible degree."

THE FIRST VOLUME OF A NEW SERIES OF ELEMENTARY COMMERCIAL CLASS-BOOKS.

Globe 8vo, 3*s.* 6*d.*

THE HISTORY OF COMMERCE IN EUROPE. By H. DE B. GIBBINS, M.A.,

Assistant Master at the High School, Nottingham. With Maps.

*** This little work is an instalment of a series of books on Commercial Education which have been designed to meet the growing demands for Commercial Education in our Higher Schools. Among the subjects included will be Commercial Law, Commercial Arithmetic, Commercial Geography, and care will be taken to make the series as thoroughly comprehensive and useful as possible. The present volume is the only history of European commerce that exhibits the growth and development of trade from the earliest times to the present day in a concise and complete form. The author has aimed at connecting the history of commerce with the growth of each nation in political power.*

WITH PREFACE BY DR. A. R. WALLACE.

8vo, Cloth, 14*s.* net.

THE HISTORY OF HUMAN MARRIAGE. By EDWARD WESTERMARCK, Ph.D.,

Lecturer on Sociology at the University of Helsingfors.

I have seldom read a more thorough or a more philosophic discussion of some of the most difficult, and at the same time interesting, problems of anthropology. . . . On some points Mr Westermarck has arrived at different and sometimes diametrically opposite conclusions from those of Darwin, Spencer, Morgan, Tylor, Lubbock, and he has done so after a most complete and painstaking investigation of all the available facts

With such an array of authority on the one side and a hitherto unknown student on the other, it will certainly be thought that all the probabilities are against the latter. Yet I venture to anticipate that the verdict of independent thinkers will, on most of these disputed points, be in favour of the new comer who has so boldly challenged the conclusions of some of our most esteemed writers. Even those whose views are here opposed will, I think, acknowledge that Mr. Westermarck is a careful investigator and an acute reasoner, and that his arguments, as well as his conclusions, are worthy of the most careful consideration.

Every reader of the work will admire its clearness of style and the wonderful command of what is to the author a foreign language.—From Dr. WALLACE'S Preface.

TIMES:—"Very learned and elaborate, scientifically conceived and scientifically executed. It should command the serious attention of all scientific students of sociology."

NEW PART OF MR. BUCKTON'S MONOGRAPH OF THE CICADÆ.

UNIVERSITY COLLEGE, BRISTOL.

The SESSION 1891-92 will begin on OCTOBER 8. The College supplies for Persons of either Sex, above the ordinary School Age, the means of continuing their Studies in SCIENCE, LANGUAGES, HISTORY, LITERATURE, and THEORY of MUSIC. The CHEMICAL, PHYSICAL, ELECTRICAL, ENGINEERING, GEOLOGICAL, and BIOLOGICAL LABORATORIES are open Daily. The Engineering Department includes Civil, Mechanical, Electrical, and Mining Engineering, Surveying and Architectural Work: and special arrangements for practical work have been made with various Engineers in and near Bristol. Several SCHOLARSHIPS are tenable at the College.

ENGINEERING EDUCATION.

Prof. J. RYAN, M.A., LL.M. (Camb.). D.Sc. (Lond.).

UNIVERSITY COLLEGE, BRISTOL.—Courses of Civil, Mechanical, Electrical, and Mining Engineering. Mineralogy and Applied Geology for Civil and Mining Engineers. Facilities are offered in the way of College Scholarships, Engineering Works Scholarships, and special arrangements for entrance into professional life.

CALENDAR, containing full information, price 1s. (by post, 1s. 3d.)

There will be about 15 vacancies in October. Applications, with references, should be made as early as possible to the SECRETARY, from whom Prospectus and particulars of residence in Clifton may be obtained.

JAMES RAFTER, Secretary.

BRITISH ASSOCIATION

FOR THE

ADVANCEMENT OF SCIENCE,

22 ALBEMARLE STREET, LONDON, W.

The NEXT ANNUAL GENERAL MEETING will be held at CARDIFF, commencing on WEDNESDAY, AUGUST 19.

PRESIDENT-ELECT:

WILLIAM HUGGINS, Esq., D.C.L., LL.D., F.R.S., Hon. F.R.S.E., F.R.A.S.

NOTICE TO CONTRIBUTORS OF MEMOIRS.—Authors are requested to give notice before AUGUST 1 of their intention to offer Papers.

Information about Lodgings and other Local Arrangements may be obtained from the Local Secretaries, Bank Buildings, Cardiff.

G. GRIFFITH, Assistant General Secretary.

TWO ENTRANCE SCHOLARSHIPS in

NATURAL SCIENCE, of the value of 125 Guineas (*i.e. a Free Admission*) and £60, are awarded annually in OCTOBER at ST. THOMAS'S HOSPITAL MEDICAL SCHOOL, London, S.E.

For Particulars, apply to Mr. G. RENDLE, Medical Secretary.

E. NETTLESHIP, Dean.
G. H. MAKINS, Vice-Dean.

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR.

AGRICULTURAL DEPARTMENT.

An ASSISTANT LECTURER in AGRICULTURE will be appointed in SEPTEMBER next, for one year, at a Salary of £120.

Applications must be sent in on or before SATURDAY, SEPTEMBER 5, to the undersigned, from whom information as to conditions of Appointment and Duties may be obtained.

W. CADWALADR DAVIES, Secretary and Registrar.

University College of North Wales, Bangor,
July 1, 1891.

THE AGRICULTURAL COLLEGE, ASPATRIA.

PRINCIPAL—DR. H. J. WEBB, B.Sc.

Thorough practical and scientific Training in Agriculture. Preparation for the Colonies. Students gained the First, Third, and Fourth Scholarships of the Royal Agricultural Society, 1888; First in Agriculture Junior Scholarships, 1889; First in Agriculture Senior Scholarships, 1890.

Just Published, in Demy 8vo, 62 pp., Price 1s.

SOME THOUGHTS ON SUBJECTS ASTRONOMICAL

(THE ORIGIN OF THE PLANETS AND THEIR FACES, THE SUN AND STARS, COMETS, MOONS, LIGHT AND HEAT, &c.).

Second Edition, with Notes.

By JOHN ROMANES, B.S.C.

Edinburgh: DAVID DOUGLAS, 10 Castle Street.

LIVING SPECIMENS FOR THE MICROSCOPE.

Algæ, Infusoria, Rotifera, Entomostraca, Polyzoa, and other examples of "Pond-life" are supplied at 1s. per Tube, Post free, with Drawing & Description. Volvox globator, Stentor cæruleus, Brachionus rotundus, Plumatella repens, and Paludicella Ehrenbergi now good. Amœba, Protococcus, Vorticella, Hydra, Crayfish, &c., for Students of Biology.

List Post Free.

UNIVERSITY COLLEGE OF NORTH WALES (BANGOR).

SESSION 1891-92 will open on SEPTEMBER 29.

DEPARTMENTS of PHYSICS, CHEMISTRY, and BIOLOGY.

PHYSICS ..... { Professor, A. GRAY, M.A.
Demonstrator, D. M. LEWIS, M.A.

CHEMISTRY ... { Professor, J. J. DOBBIE, M.A., D.Sc.
Demonstrator, G. MACGOWAN, Ph.D. (Leipzig.

BIOLOGY ..... Professor, R. W. PHILLIPS, M.A., B.Sc.

The Classes and Laboratory Courses of this College are arranged to meet the requirements of Students of Practical Science, as well as of Students preparing for University and other Examinations. Two Years of the Three Years' Course required for Graduation in Science at the University of Edinburgh may be taken at this College, and the Lectures in Chemistry, Botany and Zoology are recognized by the Universities of Edinburgh and London as qualifying for the Medical Degrees of those Universities. One Year of *Medicine* may be taken at this College.

The extensive Laboratories (Physical, Chemical, and Biological) are well equipped for Study and Research.

In the Physical Department a Steam-Engine and Dynamo-Electric Machinery, &c., have been provided for the Teaching of Electrical Engineering. A Special Course has been arranged in this subject.

Laboratory Fees (*per Term*)

on the scale of £1 1s. for six hours a week, in each Department.

A considerable number of Scholarships and Exhibitions are open for Competition at the beginning of each Session, and several are awarded at the close of each Session on the result of the Year's work.

For full information as to Science and Arts Courses, apply for Prospectus to the REGISTRAR,

W. CADWALADR DAVIES.

Bangor, July 1, 1891.

THE ENTOMOLOGIST'S MONTHLY MAGAZINE.

Price Sixpence, Monthly.

Edited by C. G. BARRETT, J. W. DOUGLAS, W. W. FOWLER, M.A., F.L.S., R. MCLACHLAN, F.R.S., E. SAUNDERS, F.L.S., and H. T. STAINTON, F.R.S.

This Magazine, commenced in 1864, contains standard articles and notes on all subjects connected with Entomology, and especially on the Insects of the British Isles.

Subscription—Six Shillings per Annum, post free.

London: GURNEY & JACKSON (Mr. Van Voorst's Successors), 1 Paternoster Row.

N.B.—A Second Series was commenced with the Number for January 1890.

SIMPLE BUT EFFECTIVE.

McLEOD'S SUNSHINE RECORDER.

This ingenious instrument, which is the invention of Prof. McLeod, F.R.S., of Cooper's Hill College, Staines, consists of a cylindrical metallic camera, opposite to the lens of which is a thin glass sphere silvered inside. The sphere is mounted on a slide provided with rack and pinion for focussing the image of the sun on the sensitised paper placed in the base. The instrument must be placed with its vertical plane in the meridian and inclined with the sphere upwards so that the axis of the camera makes an angle with the horizontal equal to the latitude of the place at which it is set up. The support is constructed to suit the latitude; the observer has merely to place the instrument in the meridian.

PRICE £6 15s.

Further Particulars on Application to the Maker,

JAMES J. HICKS,

8, 9, & 10 Hatton Garden, London, E.C.

THURSDAY, JULY 16, 1891.

ORGANIZERS OF TECHNICAL EDUCATION IN CONFERENCE.

THE progress that has been made during the past year by English County Councils in the application of their grants under the Local Taxation Act to purposes of technical education is attested by the map which accompanies the fourth Annual Report of the National Association for the Promotion of Technical and Secondary Education, and which we reproduce. It will be seen from this map that the counties which have determined to use the whole of the new fund for education form a large majority of the whole number both in England and Wales; and that London and Middlesex enjoy an unenviable, and we hope temporary, distinction, in having been the only counties to grab for the rates the whole of the money which might have been used to organize the secondary and technical education of their districts.

But while the map and the Report offer sufficient evidence of the good intentions of the County Councils, the solid progress already achieved is still more emphatically shown by the Conference of organizing secretaries which followed the annual meeting of the Association on the 3rd of this month. The very post of organizing secretary is the creation of the past few months. A year ago no county had dreamt of appointing an official to look after its education, and the Technical Instruction Act was only in operation in a few scattered centres. Now nearly twenty counties and county boroughs have special educational departments, with paid organizing secretaries. We need hardly point out the wisdom of making such appointments, in view of the unwonted duties cast on County Councils by recent legislation. The task is one which needs all the ability which is available, and this ability is of a highly specialized character, not to be expected of the average County Councillor or Clerk of the Peace, who besides have not the time for the necessary detailed work of organization. To leave the work to clerks would be to court failure, for the work to be attempted within the next few years must be largely tentative, and the direction of the experiments must be in the hands of men of knowledge, ideas, and resource, as well as of tact and judgment.

The selection of such men is not easy, and we are glad to find that the secretaries of the Technical Association are prepared to suggest candidates to County Councils which may be in need of them. The appointments made hitherto have been of two kinds: as temporary organizers, to inquire into claims and applications, to visit every district in the county, and to draw up a detailed scheme as the result of such inquiry; and as permanent secretaries to the Technical Instruction Committees, charged with the work of carrying out the schemes and inspecting the instruction, either personally or through the employment of experts.

About two-thirds of the gentlemen who had been appointed up to the date of the Conference accepted the invitation to be present, the districts represented being Lancashire, Cumberland, Surrey, Sussex, Derbyshire, Devonshire, Oxfordshire, Nottinghamshire, and Hampshire, besides a few county boroughs. The Conference was private and informal, its object being rather the interchange of views and the comparison of notes than the adoption of any formal resolution.

The subject chosen for consideration was the relation of the local taxation grant to secondary schools—the most difficult, as well as the most important, of the questions with which the organizer finds himself face to face when preparing a scheme. Since Matthew Arnold wrote, the disgraceful condition of secondary education in England has been a common-place; but how inefficient many of the schools are, and what tracts of country are entirely without even such facilities as they offer, is probably scarcely realized by any except those who have made a minute study of the educational wants of an average county. The country grammar-school, with small endowment and ill-paid and lethargic head master assisted by a worse paid and more inefficient usher, is all that stands for secondary education in many a market-town. Many are without even the semblance of a school above the elementary rank, and the mass of the inhabitants, it is to be feared, hardly feel the want of anything more. Here and there an energetic master or governing body has succeeded in building up a good school in despite of local apathy and lack of funds, but the fee has to be pitched at a point which excludes wage-earners, and such schools are consequently "middle," not only in the character of their instruction, but also in the class by which they are attended. Meanwhile, the clever boy of the village national school, who might profit the nation by his brains and energy, is doomed, for lack of opportunity, to leave school at twelve for the hopeless rut of farm labour.

A country-side the general education of which is as here described is not a promising field for special technical instruction. A stupid set of uneducated farmers, and a scarcely less stupid class of uneducated labourers, form hardly a good soil in which to plant lectures on agricultural chemistry or the natural history of insect pests. And thus thoughtful observers have been driven everywhere to the conclusion, no less in country than in town, that access to good secondary schools is an even more crying need at the present day than the specialized instruction to which, indeed, a sound general education is the necessary preliminary.

What, in short, is wanted, is that within reach of every inhabitant of every county should be a good secondary school, with fees such as may be reasonably expected to be paid by small farmers and tradesmen, and to which all sons of artisans and labourers who can pass a reasonable examination before the age of twelve can have access by means of scholarships.

The question before the Conference was the best means of promoting this object under the powers given by the Technical Instruction Acts. It will be remembered that the definition of technical instruction in the Act of 1889 is sufficiently wide to cover most of the subjects taught in a secondary school, and it is therefore clear that aid can be given to such schools, provided that the County Council can be represented on the governing bodies, and that the schools are not conducted for private profit. As regards the erection of new schools, it is doubtful if the whole work of building could be undertaken, even if desired, by

Digitized by Google

Digitized by Google

secondary schools, or to the discretion of the teachers of the elementary schools, elicited some difference of opinion; but on the whole the Conference favoured the plan of examination by a board appointed by the County Council, acting as far as possible in co-operation with the head masters of the secondary schools of the county. On one point all were agreed: viz. that there should be two examinations, or at least two standards—one for the country districts and the other for the towns—lest the whole of the scholarships should be monopolized by the most favoured districts. The opinion was also expressed that it might be sometimes desirable (as apparently would not be illegal under the Technical Instruction (Amendment) Act, 1891) to make scholarships tenable at certain efficient private profit schools, where no public schools are available, although such schools are debarred from receiving direct assistance. Such a course, however, would have to be adopted with the utmost caution.

Finally, the Conference considered the relations of the County Councils to the Technical Association, and a unanimous opinion was expressed in favour of a closer connection, while a suggestion was thrown out for the establishment of a quarterly journal registering the progress made in the various counties, a proposal which we are glad to hear is receiving the careful consideration of the Association.

Altogether, the discussion was felt to be of considerable value to those who have the practical work of organization in hand. We hope that such a Conference will be held annually, even if not more often, for in the novel work which lies before the County Councils points of difficulty will continually occur, on which consultation will be most useful. By the way, why should not the organizing secretaries form a permanent Association, on the model of the two Associations of Head Masters?

THE EVOLUTION OF ANIMALS.

L'Évolution des Formes Animales, avant l'Apparition de l'Homme. By F. Priem. 384 pages. Illustrated. (Paris: Baillière et Fils, 1891.)

IN this addition to the series of volumes known as the "Bibliothèque Scientifique Contemporaine," we have a worthy companion to Prof. Gaudry's "Les Ancêtres de Nos Animaux," published three years ago. To some extent, indeed, the ground is covered by M. Gaudry's more ambitious "Les Enchaînements du Monde Animal," but since the latter is in three volumes, the present work ought to find numerous readers who might be repelled by the length of the other. Moreover, the work before us has the advantage of treating each group of animals throughout geological time in consecutive form, whereas in the "Enchaînements" the Palæozoic Invertebrates are described in one volume, and those of the Secondary period in another, while the Tertiary forms are not recorded at all. Again, our author enters much more fully into the probable origin of one group from another than is the case in Gaudry's work. It is true, indeed, that in most cases these views are not original; but since they are generally taken from the highest authorities on the several groups, they will commend themselves the more strongly to students. In most works on palæontology too little attention is, in our opinion, generally given to the evolution of the various groups of the Invertebrata from one another, and we can, therefore, give a hearty welcome to a volume like the present which is mainly devoted to this fascinating subject.

We need hardly say that Prof. Priem is an out-and-out evolutionist; and we trust that we shall not disparage his work by observing that in some cases—apparently carried away by the very natural desire to make the most of his subject—he appears to have gone rather too far, stating as facts what are at best but probable hypotheses. For instance, we find it definitely stated on p. 273 that the Stegocephalous (Labyrinthodont) Amphibians had a functional parietal eye, whereas there is, of course, no actual proof that this was the case.

The work is rendered attractive by the large number of woodcuts with which it is illustrated. We regret, however, that in some cases—and more especially among the Vertebrates—the execution of these figures is by no means satisfactory. Moreover, in the chapters devoted to the Vertebrates (some of which are the weakest portions of the work) there are figures which are not only bad, but are utterly untrue to nature. Thus on p. 266 the old figure of *Coccosteus*, with the maxillary bone doing duty for the mandible, once more reappears; while on p. 301 we have the reproduction of Goldfuss's erroneous restoration of *Pterodactylus crassirostris*, which is unfortunately given as an illustration of the short-tailed genus *Pterodactylus*, whereas that particular species belongs to the long-tailed genus *Scaphognathus*.

We notice that in many instances M. Priem gives his authority for his statements as to the phylogeny of particular groups, whereas in other cases such references are omitted. This is to be regretted, since it is often somewhat difficult to find out whether the author is promulgating his own views, or quoting those of others.

The volume commences with an introductory chapter on palæontological evolution, in which the phylogeny of the horse, and the well-known passage of *Paludina neumayri* into *P. hœrnesi* are instanced as the best examples we have of the derivation of one form from another. Following this chapter, we have the various groups of animals treated in detail, commencing from the lowest. In the main the classification adopted is fairly well up to date, although we shall note some instances where the author departs from the more usual modern arrangements.

For example, in treating of the classification of the Sponges on p. 36, the author disregards Prof. Sollas's separation of the Calcareous Sponges (Calcispongiæ) as a group of equal value with all the others (Plethospongiæ), so that we find the Soft, Horny, Flinty, and Calcareous Sponges ranked as equivalent groups. Again, in the Cœlenterates (or, as we prefer to call them, Zoophytes), the Palæozoic Corals are still classed under the primary divisions of Tabulata and Rugosa; the former group including such different forms as *Favosites* (belonging to the Zoantharia) and *Heliolites*, *Halysites* and *Chætetes* (usually referred to the Alcyonaria). Later on, however, pp. 62-64, the author recognizes *Heliolites* and its allies as the ancestors of the modern coral-like Alcyonarians, such as the Organ-pipe Coral (*Tubipora*), and we there-

Digitized by Google

fore fail to see his reasons for adopting the antiquated classification.

Some of the most interesting chapters in the volume are those devoted to the evolution of the Echinoderms, the author adopting Neumayr's view that the Palæozoic Blastoids, as well as Crinoids, Sea-Urchins, and Star-fishes, are all separate branches springing from the Cystoids of the Palæozoic. The figures illustrating the gradual specialization of the Sea-urchins from the old Palæoechinoids, with their numerous rows of interambulacral plates, through the Triassic *Tiarechinus*, and thence to the Neocomian *Tetracidaris*, with its two rows of apical interambulacrals splitting into four near its equator, and thence to the modern "regular" Urchins, strike us as particularly well selected. Equally instructive is the transition from the "regular" modern Urchins (Neoechinoids) to the "irregular" forms—at first with the retention of the masticating apparatus, and subsequently with its loss.

Merely noticing that full justice is done to Neumayr's views regarding the phylogeny of the Brachiopods, we pass to the Mollusca, which we find treated in considerable detail and well illustrated. The author adopts the modern view of separating *Dentalium* as a distinct order (Scaphopods) from the Gastropods, and considers that both Pelecypods (Bivalves) and Scaphopods are derived from the latter. Nothing is said as to the origin of the Gastropods themselves, or, indeed, of the Cephalopods—probably for the very sufficient reason that nothing definite is yet known. In regard to the mutual relations of the various groups of Cephalopods, the author comes to the conclusion that the Ammonites should form a distinct order, "Ammonoidea," to be placed between the Tetrabranchiates (Nautilus) and Dibranchiates (Cuttlefish). Since, however, he adopts the view that their shells were really external, and that they are probably descended from Nautiloids, there seems but little necessity for this third order. The gradual increasing complexity in the sutures as we pass from Goniatites to Ceratites, and from the latter to true Ammonites, is held sufficient to prove the descent of the latter from the former; while Goniatites are considered to be the direct offshoots from Nautiloids, which are themselves derived from straight forms like *Orthoceras*. It would require too much space to enter on the consideration of the relations of the various genera of Ammonites to one another; but we may mention that the author fully adopts the modern views, such as the evolution of the keeled *Amaltheus* of the Jurassic from *Ptychites* of the Trias, and also that the uncoiled forms (*Hamites*, *Scaphites*, &c.) have had several distinct points of origin from true Ammonites. And here we may take the opportunity of mentioning that the terms *Ægoceras* and *Haploceras* applied to genera of Ammonites, are preoccupied by two well-known genera of Mammals, and therefore require changing. In regard to the Dibranchiate Cephalopods, it is considered that Belemnites have been derived from forms allied to Goniatites, and have themselves given origin to the modern Cuttle-fish. If this be the true phylogeny of the Cephalopods, it indicates a gradual increase in the complexity of the shell of the Tetrabranchiates, till it attained its maximum in the Jurassic and Cretaceous. Then the total disappearance of all the external-shelled forms with the exception of the *Nautilus;* while at the same time the Dibranchiates were gradually tending to develop less and less complex internal shells, till these culminated in the simple "pens" and "bones" of the modern cuttles and squids.

Coming to that portion of the work devoted to the Vertebrates, we find, as already mentioned, that the author has been in some places less successful than in the earlier chapters. We have already alluded to the misleading nature of one of the figures in the chapter on fishes, and we have to add that several of the few others with which that chapter is illustrated are highly unsatisfactory. It is probable, indeed, that the author had no opportunity of seeing the second volume of the "British Museum Catalogue of Fossil Fishes" before passing his proofs, as otherwise he would doubtless have modified some of his statements.

In his remarks on the difficulty of distinguishing between Dipnoid and Ganoid fishes (p. 265), the author seems to be totally unaware of the difference between the "autostylic" skulls of the former and the "hyostylic" of the latter; and when, on p. 267, he states that the Dipnoids are a lateral branch of the Crossopterygian Ganoids, he is directly at issue with the writer of the Museum Catalogue, who states (p. xx.) that, "concerning the evolution of the Dipnoi, palæontology as yet affords no information." Again, although Prof. Cope's observations as to the primitive structure of *Pteraspis* and its allies are referred to, we doubt whether the suggestion that the opening on the dorsal side of the head-shield corresponds to the aperture of a parietal eye will commend itself to the students of ichthyology. The chapter on the Batrachians is all too short; and, bearing in mind their resemblance to the Dipnoids in the autostylic structure of the skull, it is scarcely safe to make the statement (p. 282) that they are derived directly from Ganoids.

From his treatment of reptiles we fear that the author has but a very faint conception of the nature of a Theriodont or a Dicynodont, or else he would surely have made more of their affinity to the Batrachians on the one hand, and to Mammals on the other; while he would have also omitted any reference to the purely adaptive resemblance existing between the skull of *Udenodon* and that of a turtle. M. Priem might also have informed his readers that Dicynodonts are not confined to Africa. On the other hand, we are pleased to see that M. Priem rejects the heresy propounded by some of his countrymen, that Ichthyosaurs were derived primitively from marine reptiles, in favour of the more rational view of their near relationship to the Rhynchocephalians. In stating that the Plesiosaurs are likewise related to the Rhynchocephalians, the author is in accord with modern views, although he should also have referred to the many indications of affinity presented by these reptiles to the Chelonians. When, however, it is stated, on pp. 295, 296, that the latter were probably derived from the toothless Dicynodonts (*Udenodon*), the author at once proclaims his ignorance of some of the leading features of reptilian osteology. The statement on p. 297, that the gigantic Siwalik tortoise had a shell measuring four metres in length, leads us to wonder when this fiction will finally disappear from text-books. The author's treatment of

Digitized by Google

the Pterodactyles and Dinosaurs calls for no separate mention, although we are led to wonder why the Crocodiles are so widely separated from these groups.

The whole chapter on birds is decidedly feeble; and we must certainly take exception to the statement that *Hesperornis* and *Ichthyornis* respectively connect *Archæopteryx* with the Ratitæ and Carinatæ.

Turning to the last chapters, on the Mammals, we find the author adopting the view that the Monotremes have had an origin totally separate from the other two subclasses. We then have a notice of the Secondary Mammals, in which we observe a lamentable lack of attention to recent work on their affinities, and also to the synonymy of the various genera. We also notice that the Jurassic *Plagiaulax* and its allies are still referred to the Diprotodont Marsupials (p. 327); so that on these points the author's evolutionary views are totally out of date. Following the Marsupials, we have a very fair, although brief, account of the most recent conclusions on Mammalian phylogeny, which needs but few remarks. We notice, however, that the author adopts M. Boule's views as to the dual origin of the *Canidæ*, according to which the Foxes (Alopecoids) are considered to have originated from *Cynodictis*, while the Wolves, Jackals, and Dogs (Thooids) trace their descent to *Amphicyon*. To ourselves, indeed, it has always appeared difficult to understand how these two groups of *Canidæ* have become so much alike if they had this dual origin; and this difficulty is increased by the author's statement that those Thooids known as *Cyon* differ from the other members of that group in having originated from *Cynodictis*.

On p. 343 the author makes a slip in stating that the Hydracoidea are now represented only by a single genus; while later on he appears to be uncertain whether the Siwalik beds should be regarded as Upper Miocene (pp. 349, 350) or Upper Pliocene (p. 366). Again, we notice on p. 353 some want of acquaintance with the recent literature relating to the ancestry of the horse, *Orohippus* being identified with *Pliolophus*, whereas the latter is really the same as *Hyracotherium*, while the former is identical with *Pachynolophus*. We are in full accord with the author when he states, on p. 361, that *Chalicotherium* (with which the supposed Edentate *Macrotherium* is now known to be identical) is an aberrant Ungulate, although we must be permitted to differ from him when he adds that it shows signs of affinity with the Edentates.

We must likewise take exception to the statement, on p. 370, that the Indian Nilgai is in any sense the progenitor of the Oxen; while the view expressed on the same page, that the Buffaloes, Bisons, and true Oxen have severally originated from three distinct groups of Antelopes, can be only regarded as another instance of the author's partiality for multiple phylogenies. Although M. Priem is careful not to commit himself to the view that the Cetaceans have been derived from the extinct Enaliosaurian reptiles, yet the prominence which he gives to the statement of that view may be taken as a sign that he has not thoroughly purged himself from that heresy.

Finally, although we have felt bound to call attention to a certain amount of imperfection in the later chapters, yet, as a whole, we can conscientiously recommend the work before us to those readers who are desirous of obtaining in a compact form a summary of the evidence afforded by palæontology of the progressive evolution of animal forms. R. LYDEKKER.

METALLURGY.

Leçons sur les Métaux. Par Prof. Alfred Ditte. (Paris: Dunod, 1891.)

Traité pratique de Chimie Métallurgique. Par le Baron Hans Jüptner von Jonstorff. Translated from the German by M. Ernest Vlasto. (Paris: Gauthier-Villars, 1891.)

THESE two volumes, recently published, are both of unusual interest. The first, by Prof. Ditte, who is well known to English readers by his "Exposé de quelques Propriétés générales des Corps," may be said to mark a new departure in teaching the chemistry of metals. He points out that the principles of thermochemistry do not merely enable reactions to be explained, but to be predicted, and, on the other hand, when two sets of reactions are simultaneously possible, the laws of dissociation render it possible to rigorously define the conditions of equilibrium which are established in the chemical "systems" under consideration. It is often possible, with the guidance afforded by these laws, to say, in the absence of direct experiment, why one reaction is impossible and another certain to occur; or why a certain reaction begins without difficulty, and is arrested at a definite stage; or why a reaction which takes place readily under certain conditions cannot be effected under others that do not appear to differ greatly from those which were favourable to it. As a pupil of Deville, the author might have been expected to develop, in a treatise such as this, the teaching of his great master, and he has admirably performed his task. The classification of the work is excellent, the metals being first considered collectively, and then in detail with numerous tables of the data and constants which are so frequently required by metallurgists.

The work begins with a very clear account of Berthelot's labours in *mécanique chimique*, special care being devoted to the description of the calorimetric investigations, and to the appliances adopted in these important researches.

It appears to be a great advance for us in this country to read a chemical treatise in which the thermal values of the equations are stated in calories, side by side with the formulæ. As the book is too long to review in detail, it may be well to indicate the nature of one section only, as showing the author's care and thoroughness in the selection and arrangement of the materials. Take, for instance, the few pages devoted to carbides. The author points out that carbon in uniting with metals sometimes gives rise to the formation of true compounds, and at others to solutions of carbon in the metal. He then describes the orange-yellow product obtained by the action of carbon on metallic copper, and passes to the association of carbon with nickel, which does not confer upon nickel the property of being hardened by rapid cooling. The definite carbides of manganese, as well as the indefinite associations of carbon with iron and manganese, receive due attention,

Digitized by Google

and the author proceeds to deal with the carbides of iron, and finally with the well-defined carbides of niobium and tantalium, which have respectively the formulæ Nb_2C_2 and Ta_2C_2.

A terse description is then given of the work of Troost and Hautefeuille on the heat of formation of carbides of iron and manganese, which led to the conclusion that the union of carbon and iron is attended with absorption of heat, while in the case of the union of carbon and manganese heat is evolved, the evidence leading to the belief that Mn_3C is a true compound possessing considerable stability. The action of heat on carbides is then dealt with, and a brief, but sufficient, reference is made to Forquignon's work on the action at a high temperature of hydrogen on cast-iron. The section concludes with a description of the modes of preparing carbides, and with a sketch of the formation and properties of the nitrocarbides, more especially those of niobium and titanium.

The sections of the work devoted to the consideration of tellurides, arsenides, and antimonides, are equally good. With regard to individual metals, in the portions of the work as yet published, only potassium, rubidium, cæsium, ammonium, thallium, sodium, lithium and the metals of the alkaline earths, barium, strontium, and calcium are dealt with, but sufficient evidence of the merits of the book has been given in this brief review to show that the rest of it will be gladly welcomed, for Prof. Ditte has earned his place among the great metallurgists of France.

We should be grateful for curves indicating the effect of definite elements on the physical constants of metals.

Baron Jonstorff's book is of an entirely different character, though it is not, in its way, less excellent or useful. He says that it issues from an ironworks, and is addressed to practical metallurgists. Its aim is, however, somewhat different from that of most treatises on analytical chemistry, the author's intention being not merely to guide the chemist in his analytical methods, but to enable a blast-furnace manager or an iron-master to realize what kind of services the laboratory can render, what questions relating to the routine of work the analyst can solve, and, above all, in what way the questions should be put.

The author deals with the more important special methods of analysis, and of assaying iron and steel, and he gives due attention to the examination of refractory materials—slags, fuel, and gaseous products—and his method is singularly clear and precise. An appendix gives tabular statements which will be useful in daily work.

The book, as a whole, shows incidentally the great difference between the works-laboratory of the present day and that of twenty years ago. There is still much room for improvement, no doubt, but the laboratory of an ironworks has, in many cases, ceased to be little better than a shed, erected, say, behind the boiler-house, with an analyst and a few boys as the scientific staff.

Those who have visited the author in his beautifully situated Styrian works, and have seen his manipulation, as the reviewer has, will appreciate the excellence of his labours, and will be glad that a good translation into French will make their results more generally known.

W. C. ROBERTS-AUSTEN.

BACTERIA AND THEIR PRODUCTS.

Bacteria and their Products. By Sims Woodhead, M.D. Published in the "Contemporary Science Series." (London: Walter Scott, 1891.)

SCARCELY a year passes in England, France, or in Germany, without the publication of one or more treatises on the fascinating subject of bacteriology. Many of the more recent of these works have been written for the general reader rather than for the student, and have shown a considerable want of accuracy and lucidity, a circumstance which can only be accounted for by the fact that accomplished bacteriologists have not been their authors.

We have now before us "Bacteria and their Products," a work which we might infer from a glance at the cover, and general arrangement, to be certainly intended for the general reader. This view is strengthened by the several object-lessons and homely similes scattered throughout the text, with the fitness of which we totally disagree; witness, for example, the extraordinary comparison of a nodule of Actinomyces with two daisy heads placed base to base, "the sterile flowers in the centre" then corresponding to the club-shaped rays. The comparison is bad, but the botany is worse. Then there is the not very abstruse mathematical problem on p. 24, and the guide-like description of the Pasteur Institute, all intended, we must conclude, for the general reader rather than for the student.

On the other hand, there is a very large collection of facts, much information about fermentation and chemistry (although the interesting and oft-quoted experiments of Raulin are omitted), numerous references, and a very plentiful supply of formulæ, the whole requiring, in order to understand and appreciate them, a reader equipped with a thorough knowledge of the sciences bearing on the subject.

Putting this question aside, however, we candidly confess that we do not admire the style or arrangement of the book. There is a conspicuous want of lucidity, and of that accuracy of observation which one would have expected of the author. For instance, "What are Bacteria?" is the question propounded in chapter ii.; but the answer to this key-stone question is left in much doubt, as the description of the protoplasm, cell membrane, mode of division and reproduction of the "specks," is exceedingly confused. We should not choose Gram's method to demonstrate the capsules of Actinomyces, nor, indeed, any other capsules; and we have reason to doubt, after the beautiful monograph on Cladothrix by Billet, that the brown colour of that organism is due to iron. Again, what does the author mean when, speaking of cilia, he says, they "appear to develop only in those organisms that have special affinity for oxygen, for, as soon as the ciliated forms reach the surface of a fluid, they lose their cilia or they become much less active," &c.? Tables of classification are heaped in with scarcely any attempt to sift and reduce them to a form compatible with the scope of the book. Is this done because, as the author says (p. 47), "to the pathologist, however, these classifications are of comparatively little value"? We maintain that for a work of this kind the author has no right to take a one-sided view, and that to the science of

Digitized by Google

bacteriology the study of morphology is as important as any other side of the subject.

Turning to the description of actinomycosis and anthrax, we are surprised to find McFadyean taken as the guide in the former. Why is not the author his own guide? Or why does he not, at least, use the recent results of Boström? Then in "anthrax" it is stated "that at the point of inoculation in animals there is usually no evidence at all that it has been the point of entrance of the bacilli." This is scarcely compatible with a thorough knowledge of this familiar organism.

Again, in the opening chapter, a number of bacteriologists' names are mentioned. We think the author hardly does justice to those of our own country, for amongst the four names placed by the author in honourable association with the great name of Sir Joseph Lister, neither Lankester, nor Tyndall, nor Lawes and Gilbert, nor Wooldridge, nor Lingard, finds a place. And yet not only are these amongst our highest authorities, but the observations of Lankester and the experiments of Wooldridge constitute cardinal points in the history of bacteriology.

Lastly, the question of illustrations is a difficult one. There are very many photographic processes to choose from, and considering that there are only 20 illustrations, the author might have employed collotypes (compare Fränkel's atlas) or copper blocks; or, having used zinc blocks, should have had them printed on separate sheets, for it ought to be more generally known that it is of no use expecting a good impression from blocks of this description when printed on ordinary paper and in the text.

OUR BOOK SHELF.

Our Country's Flowers. By W. J. Gordon. (London: Day and Son, 1891.)

THIS volume is intended to aid beginners to ascertain the botanical name of any British wild flower or fern with which they may meet. After a list of local English plant-names, the serious work of the book begins with an explanation of how plants are classified, interwoven with which are a sufficient number of the terms used in describing plants to make the book "not too technical, but just technical enough" for the reader who desires to have a "nodding acquaintance" with the wild flowers of his own country. This is given first in a chatty style, and then repeated in a convenient tabular form. Next, the essential characters of the natural orders are given, after which the buttercup order, or Ranunculaceæ, is treated of at some length as a pattern of how identifications can be made. This is followed by a glossary of botanical terms, in some of which, in attempting a condensed and popular style, the writer has somewhat distorted the meaning. "Cambium" is erroneously described as a layer of mucilage, instead of a tissue. The characters of the natural orders are again stated, this time in alphabetical sequence, followed by a chapter on the genera, each of which is accompanied by a woodcut, intended to show its diagnostic character, but it is doubtful whether (at least in some of the orders) this is accomplished, as is also the case with some of the specific diagnoses with which the volume closes.

In the 33 coloured plates 509 species are depicted. This crowding is unsatisfactory, and tends to obscure what might otherwise be very useful. The figure on plate 23, numbered 388, may possibly be intended for 368, the stinging-nettle, or it may be some abnormal state of the inflorescence of a grape-vine. *Centranthus ruber* (204) and *Plantago lanceolata* (346) are also wonderful specimens of those plants. The artist, apparently, is amongst those who do not regard colour (unless it be the quantity thereof) as of value in discriminating species. The volume will, nevertheless, be a pleasant and useful companion to many during a country holiday, and, with the author, we hope will lead on to deeper study.

C. H. W.

A Summary of the Darwinian Theory of the Origin of Species. By Francis P. Pascoe, F.L.S., &c. (London: Taylor and Francis, 1891.)

IT is difficult to understand why the author of this pamphlet should think it worth while to remind his readers periodically that he is an opponent of Darwinism. Some space was recently devoted in these columns to the consideration of a book on the same subject by Mr. Pascoe, and the present production is nothing more than an abstract of this work, delivered in the form of an address to the Western Microscopical Club. We have no new facts nor arguments; there is the same lamentable display of misconception, and the author has simply strung together some sixteen pages of excerpts from the writings of Darwin and others, without any attempt at connected reasoning either for or against the Darwinian theory. The author's position is practically this: here is the whole animal kingdom, consisting of about 600,000 species; you must explain every detail of specific structure, down to the most insignificant, by the theory of natural selection; if you cannot do this, the theory is untenable. The whole of Mr. Pascoe's writings in connection with Darwinism amount to this, and nothing more; he has reiterated this statement, if not literally, at any rate in spirit, on every available opportunity for the last twenty years. The present pamphlet will, let us hope, for the sake of the author's reputation, be the last declaration to the same effect, for there is surely nothing gained either by Darwinism or anti-Darwinism by squandering the systematic powers which he is known to possess in picking out scraps of sentences from the "Origin of Species," &c., and publishing these things "of shreds and patches" under grandiloquent and misleading titles.

R. M.

The Business of Travel: a Fifty Years' Record of Progress. By W. Fraser Rae. (London: Thomas Cook and Son, 1891.)

THIS year the well-known firm of Thomas Cook and Son celebrate their fiftieth anniversary, and Mr. Fraser Rae has taken the trouble to write the present work in order to mark the occasion. The firm, it seems, had very small beginnings. Its history may be said to date from the day when, in 1841, Mr. Thomas Cook, walking along a country road, suddenly reflected that a certain temperance meeting at Loughborough would probably be a brilliant success if a special excursion train could be run between that place and Leicester. Apparently, no such thing as a special excursion train had ever before been heard of. The idea was carried out, and attracted so much attention that Mr. Cook—who was at that time a wood-turner—was often asked afterwards for advice in the organizing of railway excursions; and by and by he devoted himself wholly to the task of developing "the business of travel." His son has been for many years the sole managing partner, but to the elder Mr. Cook belongs the credit of having conceived the system with which his name is now associated. To what vast proportions the system has grown everyone knows; but there are probably few who know much about the various stages through which it has advanced to its present position. Mr. Fraser Rae tells the story clearly and effectively, and most readers, when they have finished his narrative, will be disposed to agree with him in thinking

Digitized by Google

that the jubilee of a firm which has played so prominent a part is an event of interest in the social history of the nineteenth century. Messrs. Cook, by their energy and enthusiasm, have given a powerful stimulus to the popular love of travel; and they may fairly claim that their establishment ranks to some extent among the influences which are tending to break down international prejudices.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Albert University.

I DESIRE to associate myself with Prof. Carey Foster and, to a great extent, with Prof. Ray Lankester in the statements made and the opinions expressed by them in your last issue. Present circumstances force me to do so as briefly as possible; but I should be the less satisfied to keep altogether silent because I had something to do with the drafting of the "Albert" charter in 1887.

For my part, that draft was never regarded as an effective solution of the problem of a University *for* London. I thought of it only as a handy weapon for forcing the appointment of a Royal Commission, and for shaking the London University Senate out of its happiness in the steady increase of untaught candidates for degrees.

A Commission was extorted; and it had the impartiality, at least, of ignorance. Its inquiry was short and hurried, yet it learned enough of what had been done for academic organization by the London Colleges, during sixty years, to condemn the sufficiency and self-sufficiency of the London University. That the Commission, notwithstanding, should first give the London University an opportunity of transforming itself for London's good, was natural and proper in all the circumstances.

We know what followed. The London University Senate was slow, very slow, to move at all towards meeting the London Colleges. But at last it woke up, and then after a time began to display a novel spirit of conciliation. Fifteen months ago, a real accommodation seemed to have been attained between the Councils of the Colleges on the one hand and the University Senate on the other. Even when the Senate thereafter, yielding to an irrelevant clamour from Provincial Colleges, decided to give these also a direct representation (in the teeth of the Commission's instruction and without warning to the London Colleges), I was one of those who here were still willing to try what could be made of the top-heavy and lumbering scheme. But trial there was never to be; for Convocation, which probably would reject any measure of reform, gathered itself up and made swift end of this one.

It looks now as if the "Albert University" were straightway to be upon us instead. I will not inquire into the agencies that have brought this result into such near view. Nor will I in your columns follow up my present and my late colleague's arguments against the prospective creation with others that seem to me of serious import. But I may be allowed to endorse emphatically what Prof. Lankester has said as to the absence of sanction by the professorial body here to the "Albert" draft charter. And nothing could be more to the point than Prof. Foster's observation that the "Albert" scheme has never been submitted to a meeting of the Governors of the College—which means, to the College as a corporate body.

Prof. Lankester is clearly right in contending that the whole question should now have been, or should still be, referred back to the Commission. I must, however, as a Scot, remark upon his assumption that the Northern Universities are professorially governed—free especially (as he urged in a former letter) from the mischievous lay influence of mere graduates. The fact is, that, ever since 1860, graduates, in "General Council" and also by direct representation in the "University Court," have not been without voice or influence; while, by the later reform of the other year, not only is graduate and other lay influence increased, but also the professorial powers of general management are largely diminished or even (as respects finance, &c.) abolished. There were more reasons than evidently Prof. Lankester knows of for curtailing the old professorial supremacy in Scotland. But it does not follow that in England, and more especially in London, there should not be a much franker recognition of professorial (that is, expert) knowledge of educational ends and means than appears in the "Albert" draft charter.

G. CROOM ROBERTSON.

University College, London.

P.S.—Since these remarks were put in print, a decision of the Privy Council has been announced in favour of an "Albert" (or "Metropolitan") University. They lose, therefore, most of whatever interest they may have had; but they may still appear, so far as I am concerned, if the Editor pleases. I regret the decision, and think the promoters of it may yet have reason to wish that their action had been less hurried. At the same time, one may acknowledge the remarkable energy and fertility of resource with which the enterprise has been conducted to its thus far successful issue.—G. C. R.

IF I may be allowed another word on this subject, I should like to say that, having been all along a keen advocate of the establishing of a strong professorial University in London, not necessarily in slavish imitation of the German system (of which I happen to know something), but combining the main features of its professoriate (of which I think I showed my appreciation in a paper read at Bath in 1888, before Section B of the British Association) with the essential elements of the present University of London, and believing that the draft charter of the Senate, which was presented to Convocation, contained in it the potentialities, out of which (with the exercise of a little common-sense to soften down such asperities as might cause friction in its initiatory working, together with a little patience to allow for the time necessary in all evolutionary changes) a strong professorial University could be developed, I voted for the Senate's scheme, and still think the adverse vote of Convocation the greatest disaster that has befallen the University in the half-century of its existence.

Of all the bitter things said by Prof. Lankester in his former letter, nothing was more to the point than his sarcastic challenge to the existing University to reform itself, if it can, with the "dead weight of graduates tied round its neck, and called Convocation." But must an institution, which has admittedly done so much good, be swamped because of the accident of a flaw in its constitution? Is there no power to remove this millstone from its neck? If anything can exceed one's admiration for Prof. Lankester's candour in penning the letter, which appears in NATURE this week (July 9, p. 222), it is the satisfaction one must feel at finding that the projected repetition of "federal futility" which is at present in a state of incubation at the Council Office, has no attraction for him. It is to be hoped that the main question will be referred back to the Royal Commission, and that the Commissioners will give such advice to the "powers that be," that the shortsighted decision of Convocation may be overruled, as Prof. Lankester has suggested twice over, and that (to use the words spoken to me, the morning after the vote, by a distinguished Oxford man, whose academical experience no one could challenge) "the Government will take up the matter, and pass an Act doing what sensible people wish to see done," by co-ordinating and harmonizing, instead of segregating, the present machinery for higher education in the metropolis, including the great medical schools.

Prof. Karl Pearson's idea of the "fusion" of the two Colleges (see NATURE, June 4, p. 102), as distinct from "federation," is splendid in theory; but will it work? Can the fluxing material be found, which shall make the iron and the clay interfuse without either Gower Street or Somerset House, or both, sacrificing those traditions which are the strongest element in that *individuality* which each values so highly and both seem so anxious to conserve?

A. IRVING.

Wellington College, July 10.

Name for Resonance.

ALTHOUGH inadvisable as a rule to correct errors in a report for which one is not responsible, there is one little mistake on p. 238 this week, which, uncorrected, may lead to the extinction of a useful suggestion.

In discussing the subject of "electric resonance" recently at Cambridge, I found that the term conveyed no correct meaning

Digitized by Google

to the untechnically instructed. Its natural meaning implies echo or reverberation, and has a definite relation to sound. Now, although a sort of reverberation or repetition is part of the effect intended to be denoted by the phrase resonance, yet the most essential feature of that phenomenon, and the one most to be emphasized in the recent extensions of the term, viz. the accord of frequency or similar tuning between two vibrators, is not connoted at all. Hence, even in acoustics the term is hardly satisfactory, while its extension to other departments of physics may be misleading.

It was suggested, however, by Dr. Arthur Myers, that the existing word *σύντονος* has almost exactly the right connotation, and has no special limitation to sound; while the derivatives *syntony*, *syntonic*, and *syntonise* may readily become English without exciting repulsion.

The adjective "symphonic," suggested by the reporter of the Physical Society, does not strike me as so good, because it specially refers to sound again, and because the word "symphony" has already another definite meaning.

July 10. OLIVER J. LODGE.

Force and Determinism.

I DO not think there are many non-physicists who will attempt to gainsay the fact that, under physical constraint, the direction of motion may be determined without affecting the quantity of the energy concerned, and without expenditure of energy. This is seen when the earth and sun revolve around their common centre of gravity, or when I twirl my stick around my finger and thumb; the earth and sun in the one case, and the ferrule and knob of my stick in the other case, being bound into one system physically. But I do think that an able and clear-headed physicist like Dr. Oliver Lodge would be doing a great service to non-physicists if he would, in your widely-circulated columns, explain and solve, shortly and in non-technical language, the difficulties which trouble some of them; aiding them, for example, to comprehend the exact force of the words expenditure of energy, and helping them to see that in all known cases of change of direction of motion such change is effected under physical constraint. It is when they are told by a certain class of metaphysicians, who quote, or misquote, physics in support of their assumptions, that physical motion is controlled by will-power or volition, always acting at right angles to direction of motion, and therefore leaving the amount of energy unchanged; it is *them*, I say, that they begin to grow restive, and to demand definite and verifiable evidence that such metaphysical constraint is (*pace* Sir John Herschel) a necessary or philosophical conception, and that it is impossible to explain the phenomena without having recourse to it. If Dr. Lodge would consent to help non-physicists in this way, and would indicate what are the "important psychological consequences" to which he alludes, he would be doing some of us a good turn. C. LLOYD MORGAN.

University College, Bristol.

As Prof. Lodge says he is glad to see that his statement, "although expenditure of energy is needed to increase the speed of matter none is required to alter its direction," called in question, and as he has so kindly answered one letter on the subject, may I ask him to criticize the following remarks?

The theory of kinematics is based on certain geometrical concepts, which may be summed up in the term space, and on the concept of time. The laws of motion, together with the assertion that mass is not a function of space or time, may logically be regarded as implicitly defining mass and force. Energy may similarly be defined, in terms of these kinematic concepts, as $\int F ds$. For I think the progress of science is tending to show that the term "potential energy" is only a cloak to cover our ignorance of the kinetic energies which for the moment have escaped our ken. But in any case the statement quoted is logically only a truism, deduced from the definitions of its terms, and is therefore indisputable in all mechanical theorems. But if it is to be applied outside the sphere of pure mechanics, the moral will lie in the application of it—that is, it will be necessary to examine, before applying it to any new subject-matter, whether the definitions from which it was deduced apply to that subject-matter or not.

For example, by the third law of motion, mechanical force only acts *between two masses*, the momenta generated in them being equal and opposite. If, therefore, psychic force is to come under the definition of mechanical force, it can only act *between* two particles. And, therefore, if psychic force is to do no work, by reason of its always acting in a direction normal to the path of a particle, it can only act between two particles whose paths happen to have a common normal—an occurrence which must be infinitely rare. EDWARD T. DIXON.

12 Barkston Mansions, South Kensington, July 4.

Magnetic Anomalies.

THE discovery of very strong magnetic anomalies between Charkov and Kursk in Russia, to which A. de Tillo has lately referred in the *Comptes rendus* and in NATURE, raises the question whether the values there observed are strictly local, or extend over a relatively wide area. Thus, it would be of great interest to know if, on moving, say, some metres away from a station, the declination and inclination hold the same value. If not, there is clearly some cause which acts at a short distance; but if constancy is observed, a great step would be taken towards the settlement of the question as to the existence of strong variations common to a wide area.

When magnetic anomalies are observed, the first thing to be done is to ascertain whether the values found in a given locality have a definite meaning—that is, whether they do not change for slight displacements; otherwise, the determination of the magnetic elements has no meaning, as it is impossible to refer them to geographical co-ordinates.

The overlooking of this precaution has often led to serious mistakes. ALFONSO SELLA.

Biella, July 4.

Physical Religion.

AS a constant reader of NATURE from its commencement, and the possessor of its forty-three and a half volumes, I venture (after reading the review of "Physical Religion" in this week's number) to ask if it is intended to develop it into a theological journal. Because, however smart it may be to abolish Abraham without "even taking the trouble to discuss" him, or to dispose of *Lux Mundi* in a contemptuous sentence, it is hardly in accordance with scientific methods.

It is curious that many "Agnostics," though by their own showing (if they would talk Latin instead of Greek) they are *Ignoramuses* at best, should be so certainly sure of everything, when a little reflection and modesty might satisfy them that as "*Know-nothings*" (in plain English) they have no more right to *deny* than to *assert*.

The standing motto of your title might be improved by the addition of "Ne supra crepidam sutor."

Hampstead Heath, July 11. B. WOODD SMITH.

SOME APPLICATIONS OF PHOTOGRAPHY.[1]

ONE of the subjects to which I propose to invite your attention this evening is the application of instantaneous photography to the illustration of certain mechanical phenomena which pass so quickly as to elude ordinary means of observation. The expression "instantaneous photography" is perhaps not quite a defensible one, because no photography can be really instantaneous—some time must always be occupied. One of the simplest and most commonly used methods of obtaining very short exposures is by the use of movable shutters, for which purpose many ingenious mechanical devices have been invented. About two years ago we had a lecture from Prof. Muybridge, in which he showed us the application of this method—and a remarkably interesting application it was—to the examination of the various positions assumed by a horse in his several gaits. Other means, however, may be employed to the same end, and one of them depends upon the production of an instantaneous light. It will obviously come to the same thing whether the light to which we expose the plates be instantaneous, or whether by a mechanical device we allow the plate to be submitted to a continuous light for

[1] Friday Evening Discourse, delivered at the Royal Institution of Great Britain, on February 6, 1891, by Lord Rayleigh, F.R.S., Professor of Natural Philosophy, R.I.

Digitized by Google

only a very short time. A good deal of use has been made in this way of what is known as the magnesium flash light. A cloud of magnesium powder is ignited, and blazes up quickly with a bright light of very short duration. Now I want to compare that mode of illumination with another, in order to be able to judge of the relative degree of instantaneity, if I may use such an expression. We will illumine for a short time a revolving disk, composed of black and white sectors; and the result will depend upon how quick the motion is as compared with the duration of the light. If the light could be truly instantaneous, it would of necessity show the disk apparently stationary. I believe that the duration of this light is variously estimated at from one-tenth to one-fiftieth of a second; and as the arrangement that I have here is one of the slowest, we may assume that the time occupied will be about a tenth of a second. I will say the words one, two, three, and at the word three Mr. Gordon will project the powder into the flame of a spirit-lamp, and the flash will be produced. Please give your attention to the disk, for the question is whether the present uniform grey will be displaced by a perception of the individual black and white sectors. [Experiment.] You see the flash was *not* instantaneous enough to resolve the grey into its components.

I want now to contrast with that mode of illumination one obtained by means of an electric spark. We have here an arrangement by which we can charge Leyden jars from a Wimshurst machine. When the charge is sufficient, a spark will pass inside a lantern, and the light proceeding from it will be condensed and thrown upon the same revolving disk as before. The test will be very much more severe; but, severe as it is, I think we shall find that the electric flash will bear it. The teeth on the outside of the disk are very numerous, and we will make them revolve as fast as we can, but we shall find that under the electric light they will appear to be absolutely stationary. [Experiment.] You will agree that the outlines of the black and white sectors are seen perfectly sharp.

Now, by means of this arrangement we might investigate a limit to the duration of the spark, because with a little care we could determine how fast the teeth are travelling—what space they pass through in a second of time. For this purpose it would not be safe to calculate from the multiplying gear on the assumption of no slip. A better way would be to direct a current of air upon the teeth themselves, and make them give rise to a musical note, as in the so-called siren. From the appearance of the disk under the spark we might safely say, I think, that the duration of the light is less than a tenth of the time occupied by a single tooth in passing. But the spark is in reality much more instantaneous than can be proved by the means at present at our command. In order to determine its duration, it would be necessary to have recourse to that powerful weapon the revolving mirror; and I do not, therefore, propose to go further into the matter to-night.

Experiments of this kind were made some twenty years ago by Prof. Rood, of New York, both on the duration of the discharge of a Leyden jar, and also on that of lightning. Prof. Rood found that the result depended somewhat upon the circumstances of the case, the discharge of a small jar being generally more instantaneous than that of a larger one. He proved that in certain cases the duration of the principal part of the light was as low as one twenty-five-millionth part of a second of time. That is a statement which probably conveys very little of its real meaning. A million seconds is about twelve days and nights. Twenty-five million seconds is nearly a year. So that the time occupied by the spark in Prof. Rood's experiment is about the same fraction of one second that one second is of a year. In many other cases the duration was somewhat greater; but in all his experiments it was well under the one-millionth part of a second. In certain cases you may have multiple sparks. I do not refer to the oscillating discharges of which Prof. Lodge gave us so interesting an account last year; Prof. Rood's multiple discharge was not of that character. It consisted of several detached overflows of his Leyden jar when charged by the Rhumkorff coil. One number mentioned for the total duration was one six-thousandth part of a second; but the individual discharges had the degree of instantaneity of which I have spoken.

It is not a difficult matter to adapt the electrical spark to instantaneous photography. We will put the lantern into its proper position, excite the electric sparks within it, causing them to be condensed by the condenser of the lantern on to the photographic lens. We will then put the object in front of the lantern-condenser, remove the cap from the lens, expose the plate to the spark when it comes, and thus obtain an instantaneous view of whatever may be going on. I propose to go through the operation of taking such a photograph presently. I will not attempt any of the more difficult things of which I shall speak, but will take a comparatively easy subject—a stream of bubbles of gas passing up through a liquid. In order that you may see what this looks like when observed in the ordinary way, we have arranged it here for projection upon the screen. [Experiment.] The gas issues from the nozzle, and comes up in a stream, but so fast that you cannot fairly see the bubbles. If, however, we take an instantaneous picture, we shall find that the stream is decomposed into its constituent parts. We arrange the trough of liquid in front of the lantern which contains the spark-making apparatus—[Experiment]—and we will expose a plate, though I hardly expect a good result in a lecture. A photographer's lamp provides some yellow light to enable us to see when other light is excluded. There goes the spark; the plate is exposed, and the thing is done. We will develop the plate, and see what it is good for; and if it turns out fit to show, we will have it on the screen within the hour.

In the meantime, we will project on the screen some slides taken in the same way and with the same subject. [Photograph shown.] That is an instantaneous photograph of a stream of bubbles. You see that the bubbles form at the nozzle from the very first moment, contrasting in that respect with the behaviour of jets of water projected into air (Fig. 1).

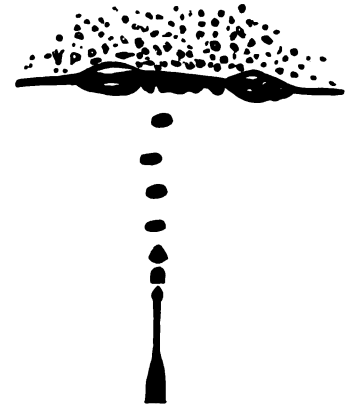

FIG. 1.

The latter is our next subject. This is the reservoir from which the water is supplied. It issues from a nozzle of drawn-out glass, and at the moment of issue it consists of a cylindrical body of water. The cylindrical form is unstable, however, and the water rapidly breaks up into drops, which succeed one another so rapidly that they can hardly be detected by ordinary vision. But by

Digitized by Google

means of instantaneous photography the individual drops can be made evident. I will first project the jet itself on the screen, in order that you may appreciate the subject which we shall see presently represented by photography. [Experiment.] Along the first part of its length the jet of water is continuous. After a certain point it breaks into drops, but you cannot see them because of their rapidity. If we act on the jet with a vibrating body, such as a tuning-fork, the breaking into drops occurs still earlier, the drops are more regular, and assume a curious periodic appearance, investigated by Savart. I have some photographs of jets of that nature. Taken as described, they do not differ much in appearance from those obtained by Chichester Bell, and by Mr. Boys. We get what we may regard as simply shadows of the jet obtained by instantaneous illumination; so that these photographs show little more than the outlines of the subject. They show a little more, on account of the lens-like action of the cylinder and of the drops. Here we have an instantaneous view of a jet similar to the one we were looking at just now (Fig. 2). This is the continuous part; it gradually ripples itself as it comes along; the ripples increase; then the contraction becomes a kind of ligament connecting consecutive drops;

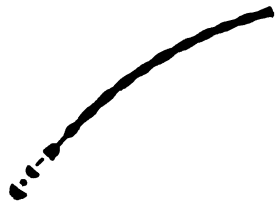

FIG. 2.

the ligament next gives way, and we have the individual drops completely formed. The small points of light are the result of the lens-like action of the drops. [Other instantaneous views also shown.]

The pictures can usually be improved by diffusing somewhat the light of the spark with which they are taken. In front of the ordinary condensing lens of the magic lantern we slide in a piece of ground glass, slightly oiled, and we then get better pictures showing more shading. [Photograph shown.] Here is one done in that way; you would hardly believe it to be water resolved into drops under the action of a tremor. It looks more like mercury. You will notice the long ligament trying to break up into drops on its own account, but not succeeding (Fig. 3).

There is another, with the ligament extremely prolonged. In this case it sometimes gathers itself into two drops (Fig. 4).

[A number of photographs showing slight variations were exhibited.]

The mechanical cause of this breaking into drops is, I need hardly remind you, the surface tension or capillary force of the liquid surface. The elongated cylinder is an unstable form, and tends to become alternately swollen and contracted. In speaking on this subject I have often been embarrassed for want of an appropriate word to describe the condition in question. But a few days ago, during a biological discussion, I found that there is a recognized, if not a very pleasant, word. The cylindrical jet may be said to become *varicose*, and the varicosity goes on increasing with time, until eventually it leads to absolute disruption.

There is another class of unstable jets presenting many points of analogy with the capillary ones, and yet in many respects quite distinct from them. I refer to the phenomena of sensitive flames. The flame, however, is not the essential part of the matter, but rather an indicator of what has happened. Any jet of fluid playing into a stationary environment is sensitive, and the most convenient form for our present purpose is a jet of coloured in uncoloured water. In this case we shall use a solution of permanganate of potash playing into an atmosphere of other water containing acid and sulphate of iron, which exercises a decolourising effect on the permanganate, and so retards the general clouding up of the whole mass by accumulation of colour. [Experiment.] Mr. Gordon will release the clip, and we shall get a jet of permanganate playing into the liquid. If everything were pefectly steady, we might see a line of purple liquid extending to the bottom of the trough; but in this theatre it is almost impossible to get anything steady. The instability to which the jet is subject now manifests itself, and we get a breaking away into clouds something like smoke from chimneys. A heavy tuning-fork vibrating at ten to the second acts upon it with great advantage, and regularizes the disruption. A little more pressure will increase the instability, and the jet goes suddenly into confusion, although at first, near the nozzle, it is pretty regular.

It may now be asked "What is the jet doing?" That is just the question which the instantaneous method

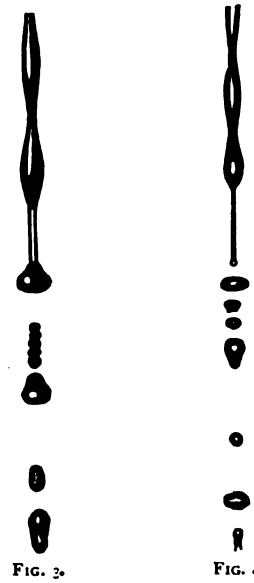

FIG. 3.

FIG. 4.

enables us to answer. For this purpose the permanganate which we have used to make the jet visible is not of much service. It is too transparent to the photographic rays, and so it was replaced by bichromate of potash. Here the opposite difficulty arises; for the bichromate is invisible by the yellow light in which the adjustments have to be made. I was eventually reduced to mixing the two materials together, the one serving to render the jet visible to the eye and the other to the photographic plate. Here is an instantaneous picture of such a jet as was before you a moment ago, only under the action of a regular vibrator. It is *sinuous*, turning first in one direction and then in the other. The original cylinder, which is the natural form of the jet as it issues from the nozzle, curves itself gently as it passes along through the water. It thus becomes sinuous, and the amount of the sinuosity increases, until in some cases the consecutive folds come into collision with one another. [Several photographs of sinuous jets were shown, two of which are reproduced in Figs. 5 and 6.]

The comparison of the two classes of jets is of great interest. There is an analogy as regards the instability, the vibrations caused by disturbance gradually increasing as the distance from the nozzle increases; but there is a

Digitized by Google

great difference as to the nature of the deviation from the equilibrium condition, and as to the kind of force best adapted to bring it about. The one gives way by becoming varicose; the other by becoming sinuous. The only forces capable of producing varicosity are symmetrical forces, which act alike all round. To produce sinuosity, we want exactly the reverse—a force which acts upon the jet transversely and unsymmetrically.

I will now pass on to another subject for instantaneous photography—namely, the soap film. Everybody knows that if you blow a soap bubble it will break—generally before you wish. The process of breaking is exceedingly rapid, and difficult to trace by the unaided eye. If we can get a soap film on this ring, we will project it upon the screen and then break it before your eyes, so as to enable you to form your own impressions as to the rapidity of the operation. For some time it has been my ambition to photograph a soap bubble in the act of breaking. I was prepared for difficulty, believing that the time occupied was less than the twentieth of a second. But it turns out to be a good deal less even than that. Accordingly the subject is far more difficult to deal with than are those jets of water or coloured liquids which one

FIG. 5.

FIG. 6.

can photograph at any moment that the spark happens to come.

There is the film, seen by reflected light. One of the first difficulties we have to contend with is that it is not easy to break the film exactly when we wish. We will drop a shot through it. The shot has gone through, as you see, but it has not broken the film; and when the film is a thick one, you may drop a shot through almost any number of times from a moderate height without producing any effect. You would suppose that the shot in going through would necessarily make a hole, and end the life of the film. The shot goes through, however, without making a hole. The operation can be traced, not very well with a shot, but with a ball of cork stuck on the end of a pin, and pushed through. A dry shot does not readily break the film; and as it was necessary for our purpose to effect the rupture in a well-defined manner, here was a difficulty which we had to overcome. We found, after a few trials, that we could get over it by wetting the shot with alcohol.

We will try again with dry shot. Three shots have gone through and nothing has happened. Now we will try one wetted with alcohol, and I expect it will break the film at once. There! it has gone!

The apparatus for executing the photography of a breaking soap film will of necessity be more complicated than before, because we have to time the spark exactly with the breaking of the film. The device I have used is to drop two balls simultaneously, so that one should determine the spark and the other rupture the film. The most obvious plan was to hang iron balls to two electro-magnets, and cause them to drop by breaking the circuit, so that both were let go at the same moment. The method was not quite a success, however, because there was apt to be a little hesitation in letting go the balls. So we adopted another plan. The balls were not held by electro-magnetism, but by springs (Fig. 8) pressing laterally, and these were pulled off by electro-magnets. The proper moment for putting down the key and so liberating the balls, is indicated by the tap of the beam of an attracted disk electrometer as it strikes against the upper stop. One falling ball determines the spark, by filling up most of the interval between two fixed ones submitted to the necessary electric pressure. Another ball, or rather shot, wetted with alcohol, is let go at the same moment, and breaks the film on its passage through it. By varying the distances dropped through, the occurrence of one event may be adjusted relatively to the other. The spark which passes to the falling ball is, however, not the one which illuminates the photographic plate. The latter occurs within the lantern, and forms part of a circuit in connection with the *outer* coatings of the Leyden jars,[1] the

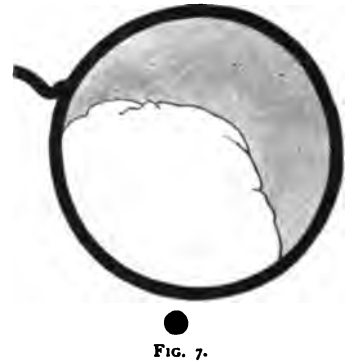

FIG. 7.

whole arrangement being similar to that adopted by Prof. Lodge in his experiments upon alternative paths of discharge. Fig. 8 will give a general idea of the disposition of the apparatus. [Several photographs of breaking films were shown upon the screen; one of these is reproduced in Fig. 7.][2]

This work proved more difficult than I had expected; and the evidence of our photographs supplies the explanation—namely, that the rupture of the film is an extraordinarily rapid operation. It was found that the whole difference between being too early and too late was represented by a displacement of the falling ball through less than a diameter, viz. $\frac{1}{4}$ inch nearly. The drop which we gave was about a foot. The speed of the ball would thus be about 100 inches per second; therefore the whole difference between being too soon and too late is represented by $\frac{1}{300}$ second. Success is impossible, unless the spark can be got to occur within the limits of this short interval.

Prof. Dewar has directed my attention to the fact that Dupré, a good many years ago, calculated the speed of rupture of a film. We know that the energy of the film is in proportion to its area. When a film is partially broken, some of the area is gone, and the corresponding potential energy is expended in generating the velocity of

[1] In practice there were two sets of three jars each.

[2] The appearance of the breaking bubble, as *seen* under instantaneous illumination, was first described by Marangoni and Stephanelli, *Nuovo Cimento*, 1873.

Digitized by Google

the thickened edge, which bounds the still unbroken portion. The speed, then, at which the edge will go depends upon the thickness of the film. Dupré took a rather extreme case, and calculated a velocity of 32 metres per second. Here, with a greater thickness, our velocity was, perhaps, 16 yards a second, agreeing fairly well with Dupré's theory.

I now pass on to another subject with which I have lately been engaged—namely, the connection between aperture and the definition of optical images. It has long been known to astronomers and to those who study optics that the definition of an optical instrument is proportional to the aperture employed; but I do not think that the theory is as widely appreciated as it should be. I do not know whether, in the presence of my colleague, I may venture to say that I fear the spectroscopists are lenses may be. In accordance with the historical development of the science of optics, the student is told that the lens collects the rays from one point to a focus at another; but when he has made further advance in the science he finds that this is not so. The truth is that we are in the habit of regarding this subject in a distorted manner. The difficulty is, not to explain why optical images are imperfect, no matter how good the lens employed, but rather how it is that they manage to be as good as they are. In reality the optical image of even a mathematical point has a considerable extension; light coming from one point cannot be concentrated into another point by any arrangement. There must be diffusion, and the reason is not hard to see in a general way. Consider what happens at the mathematical focus, where, if anywhere, the light should all be concentrated. At that point all the rays coming from the original radiant

among the worst sinners in this respect. They constantly speak of the dispersion of their instruments as if that by itself could give any idea of the power employed. You may have a spectroscope of any degree of dispersion, and yet of resolving power insufficient to separate even the D lines. What is the reason of this? Why is it that we cannot get as high a definition as we please with a limited aperture? Some people say that the reason why large telescopes are necessary is, because it is only by their means that we can get enough light. That may be in some cases a sufficient reason, but that it is inadequate in others will be apparent, if we consider the case of the sun. Here we do not want more light, but rather are anxious to get rid of a light already excessive. The principal *raison d'être* of large telescopes is, that without a large aperture definition is bad, however perfect the point arrive in the same phase. The different paths of the rays are all rendered optically equal, the greater actual distance that some of them have to travel being compensated for in the case of those which come through the centre by an optical retardation due to the substitution of glass for air; so that all the rays arrive at the same time.[1] If we take a point not quite at the mathematical focus but near it, it is obvious that there must be a good deal of light there also. The only reason for any diminution at the second point lies in the discrepancies of phase which now occur; and these can only enter by degrees. Once grant that the image of a mathematical point is a diffused patch of light, and it follows that there must be a limit to definition. The images of the com-

[1] On this principle we may readily calculate the focal lengths of lenses without use of the law of sines (see *Phil. Mag.*, December 1879).

Digitized by Google

ponents of a close double point will overlap; and if the distance between the centres do not exceed the diameter of the representative patches of light, there can be no distinct resolution. Now their diameter varies inversely as the aperture; and thus the resolving power is directly as the aperture.

My object to-night is to show you by actual examples that this is so. I have prepared a series of photographs of a grating consisting of parallel copper wires separated by intervals equal to their own diameter, and such that the distance from centre to centre is $\frac{1}{10}$ inch. The grating was backed by a paraffin lamp and large condensing lens; and the photographs were taken in the usual way, except that the lens employed was a telescopic object-glass, and was stopped by a screen perforated with a narrow adjustable slit, parallel to the wires.[1] In each case the exposure was inversely as the aperture employed. The first [thrown upon the screen] is a picture done by an aperture of eight hundredths of an inch, and the definition is tolerably good. The next, with six hundredths, is rather worse. In the third case, I think that everyone can see that the definition is deteriorating; that was done by an aperture of four hundredths of an inch. The next is one done by an aperture of three hundredths of an inch, and you can see that the lines are getting washed out. In focussing the plate for this photograph I saw that the lines had entirely disappeared, and I was surprised, on developing the plate, to find them still visible. That was in virtue of the shorter wave-length of the light operative in photography as compared with vision. In the last example, the aperture was only two-and-a-half hundredths of an inch, and the effect of the contraction has been to wash away the image altogether, although, so far as ordinary optical imperfections are concerned, the lens was acting more favourably with the smaller aperture than with the larger ones.

This experiment may be easily made with very simple apparatus; and I have arranged that each one of my audience may be able to repeat it by means of the piece of gauze and perforated card which have been distributed. The piece of gauze should be placed against the window so as to be backed by the sky, or in front of a lamp provided with a ground-glass or opal globe. You then look at the gauze through the pin-holes. Using the smaller hole, and gradually drawing back from the gauze, you will find that you lose definition and ultimately all sight of the wires. That will happen at a distance of about 4½ feet from the gauze. If, when looking through the smaller hole, you have just lost the wires, you shift the card so as to bring the larger hole into operation, you will see the wires again perfectly.

That is one side of the question. However perfect your lens may be, you cannot get good definition if the aperture is too much restricted. On the other hand, if the aperture is much restricted, then the lens is of no use, and you will get as good an image without it as with it.

I have not time to deal with this matter as I could wish, but I will illustrate it by projecting on the screen the image of a piece of gauze as formed by a narrow aperture parallel to one set of wires. There is no lens whatever between the gauze and the screen. [Experiment.] There is the image—if we can dignify it by such a name—of the gauze as formed by an aperture which is somewhat large. Now, as the aperture is gradually narrowed, we will trace the effect upon the definition of the wires parallel to it. The definition is improving; and now it looks tolerably good. But I will go on, and you will see that the definition will get bad again. Now, the aperture has been further narrowed, and the lines are getting washed out. Again, a little more, and they are gone. Perhaps you may think that the explanation lies in the faintness of the light. We cannot avoid the loss of light which accompanies the contraction of aperture, but to prove that the result is not so to be explained, I will now put in a lens. This will bring the other set of wires into view, and prove that there was plenty of light to enable us to see the first set if the definition had been good enough. Too small an aperture, then, is as bad as one which is too large; and if the aperture is sufficiently small, the image is no worse without a lens than with one.

What, then, is the best size of the aperture? That is the important question in dealing with pin-hole photography. It was first considered by Prof. Petzval, of Vienna, and he arrived at the result indicated by the formula, $2r^2 = f\lambda$, where $2r$ is the diameter of the aperture, λ the wave-length of light, and f the focal length, or rather simply the distance between the aperture and the screen upon which the image is formed.

His reasoning, however, though ingenious, is not sound, regarded as an attempt at an accurate solution of the question. In fact it is only lately that the mathematical problem of the diffraction of light by a circular hole has been sufficiently worked out to enable the question to be solved. The mathematician to whom we owe this achievement is Prof. Lommel. I have adapted his results to the problem of pin-hole photography. [A series of curves (*Philosophical Magazine*, February 1891), were shown, exhibiting to the eye the distribution of illumination in the images obtainable with various apertures.] The general conclusion is that the hole may advantageously be enlarged beyond that given by Petzval's rule. A suitable radius is $r = \sqrt{(f\lambda)}$.

I will not detain you further than just to show you one application of pin-hole photography on a different scale from the usual. The definition improves as the aperture increases; but in the absence of a lens the augmented aperture entails a greatly extended focal length. The limits of an ordinary portable camera are thus soon passed. The original of the transparency now to be thrown upon the screen was taken in an ordinary room, carefully darkened. The aperture (in the shutter) was 0·07 inch, and the distance of the 12 × 10 plate from the aperture was 7 feet. The resulting picture of a group of cedars shows nearly as much detail as could be seen direct from the place in question.

[1] The distance between the grating and the telescope lens was 12 feet 3 inches.

THE SMITHSONIAN ASTRO-PHYSICAL OBSERVATORY.

THE Smithsonian Institution, as we have already announced, has established as one of its departments a Physical Observatory which, with the instruments, has been supplied from the Smithsonian Fund. It occupies at present a temporary structure, though funds have been subscribed for a permanent building when Congress shall provide a suitable site. For the maintenance of the Observatory an appropriation has been made by Congress which became available on July 1. The actual instrumental work of the new Observatory will necessarily devolve largely upon a senior and a junior assistant, who can devote their entire time to research, and it is hoped that with the improved apparatus it will be possible to prosecute advantageously investigations in telluric and astro-physics, and particularly those with the bolometer in radiant energy.

In accepting the position of assistant secretary of the Smithsonian Institution in 1887, Mr. Langley retained the Directorship of the Observatory at Allegheny for the purpose of completing the researches begun there, and after his appointment as Secretary of the Institution, he still continued the titular Directorship, though but a limited amount of time could be spared from his official

Digitized by Google

duties at the capital. With the completion of the equipment of the little Observatory at Washington, he, however, formally resigned, on April 30, the Directorship at Allegheny, which he had held since 1887; and he will, so far as his administrative occupations permit, give personal attention to the general direction of the investigations.

The class of work which is referred to does not ordinarily involve the use of the telescope, and that which is contemplated is quite distinct from what is carried on at present at any other Observatory in the United States. The work for which the older Government Observatories at Greenwich, Paris, Berlin, and Washington were founded, and in which they are now chiefly engaged, is the determination of relative positions of heavenly bodies, and our own place with reference to them. Within the past twenty years all these Governments, except that of the United States, have established astrophysical Observatories, as they are called, which are, as is well known, engaged in the study of the heavenly bodies as distinct from their positions—in determining, for instance, not where, but what, the sun is, how it affects terrestrial climate and life, and how it may best be studied for the purposes of the meteorologist, and for other uses of an immediately practical nature.

The new Observatory is established for similar purposes. Its outfit includes a very large siderostat (recently completed by Grubb), which is mounted in such a way as to throw a beam of light horizontally in the meridian. It is intended to carry a mirror of 20 inches diameter, and is perhaps the most massive and powerful instrument of its kind ever constructed Within the dark room is mounted another large instrument—the spectrobolometer—which is, in effect, a large spectroscope with 20-inch circle reading to 5 seconds of arc, specially designed for use with the bolometer. It was made by William Grunow and Son, of New York, as the outcome of Mr. Langley's experience with smaller apparatus during his earlier investigations. The most important part of the instrumental equipment is completed by specially designed galvanometers, scales, and a peculiar resistance box; and these three instruments, used in conjunction with the bolometer, and perhaps with the aid of photography, will be employed in the investigations upon light, heat, and radiant energy in general, for which the Observatory is primarily intended, though some departments of terrestrial physics may also receive attention.

THE NEW GALLERY OF BRITISH ART.

WE believe that the Committee appointed by the Corporation to consider the question of the grant of a site on the Embankment for the new gallery will soon make its report. The *Pall Mall Gazette* of Tuesday says:—"There is a vacant piece of just one acre at Blackfriars, on the land acquired some years ago and cleared of the old City gas-works by the Corporation. This land originally cost some £260,000; and on portions of it have been erected the City of London School and Sion College. The value of the entire holding has increased to at least £550,000; so that if the proposed piece, which is valued at about £120,000, were made over by the Corporation for the Art Gallery, the City would still be a gainer of some £170,000 by the transaction."

In the meantime, public opinion is rapidly growing, not only in favour of some of our national buildings devoted to art finding a home in the City, but also against the site at South Kensington—bought for scientific purposes, and required to meet existing needs—being diverted from its proper and natural use.

Both these views are expressed in the following Memorial, which, although circulated chiefly among men of science during the last few days, contains the names of many representative men in other branches. It has been transmitted to the Lord Mayor during the present week.

Memorial to the Right Honourable the Lord Mayor of London.

WE, the undersigned, having heard that there is a possibility of the City of London finding a site on the Embankment for the National Gallery of British Art, which a munificent donor has proposed to build, venture to approach Your Lordship with our earnest request that you will yourself support, and use your best endeavours to urge upon the City authorities, the very great importance of giving effect to this proposal.

The memorial already presented to the Prime Minister will have made Your Lordship aware of the many strong objections, from the scientific point of view, to the site which was suggested for the gallery in the first instance.

It is unnecessary for us, therefore, to say more on this subject, except to remark that the greatest city in the world must be the first to suffer if, from any cause, the proper presentation of science and means for its study by its citizens are in any way crippled.

By affording a site on the Embankment, Your Lordship and the authorities you represent will be the means of preventing the lamentable result to which we have referred, and you and they will earn the gratitude of all interested in scientific progress, as well as confer a great boon on the art-loving public.

Among the signatories of the Memorial are the following:—

SIR WILLIAM THOMSON, D.C.L., LL.D., President Royal Society, Professor of Natural Philosophy, Glasgow.
DR. JOHN EVANS, LL.D., F.R.S., Treasurer Royal Society.
LORD RAYLEIGH, F.R.S., Secretary Royal Society.
M. FOSTER, M.D., F.R.S., Secretary Royal Society.
THOMAS H. HUXLEY, F.R.S., Dean of the Royal College of Science, London.
LIEUT.-GENERAL R. STRACHEY, F.R.S., C.I.E., Chairman Meteorological Council.
NEVIL STORY MASKELYNE, F.R.S., M.P., Professor of Mineralogy, University of Oxford.
SIR JOHN LUBBOCK, Bart., M.P., F.R.S., Chairman London County Council, Past-President British Association.
SIR RICHARD QUAIN, Bart., M.D., F.R.S.
SIR WILLIAM ROBERTS, F.R.S., M.D.
WILLIAM CROOKES, F.R.S., President Institute Electrical Engineers.
WILLIAM SUMMERS, M.P.
J. W. L. GLAISHER, M.A., F.R.S.
ALFRED NEWTON, F.R.S., Professor of Zoology, University of Cambridge.
T. E. THORPE, F.R.S., Professor of Chemistry, Royal College of Science, Treasurer Chemical Society.
JOHN W. JUDD, F.R.S., Professor of Geology, Royal College of Science.
WILLIAM HUGGINS, D.C.L., F.R.S., President-Elect of the British Association.
SIR G. G. STOKES, Bart., M.P., Past-President Royal Society, Lucasian Professor, University of Cambridge.
SIR HENRY E. ROSCOE, LL.D., F.R.S., M.P., Past-President British Association.
W. GRYLLS ADAMS, F.R.S., Professor of Physics, King's College, Past-President Physical Society.
J. FLETCHER MOULTON, Q.C., F.R.S.
E. A. SCHÄFER, F.R.S., Professor of Physiology, University College, London.
HERBERT MCLEOD, F.R.S., Professor of Chemistry, Cooper's Hill.
HUGO MÜLLER, F.R.S., Past-President Chemical Society.
ARTHUR W. RÜCKER, F.R.S., Professor of Physics, Royal College of Science, London, Treasurer Physical Society.
WILLIAM CAWTHORNE UNWIN, F.R.S., Professor of Engineering, City and Guilds of London Institute.
W. E. AYRTON, F.R.S., Professor of Physics, City and Guilds of London Institute, President Physical Society.

WILLIAM MORRIS.
WALTER CRANE.
W. J. RUSSELL, F.R.S., Professor of Chemistry, St. Bartholomew's Hospital, Past-President Chemical Society.
THE LORD TENNYSON, F.R.S., Poet Laureate.
HALLAM TENNYSON.

CARDINAL HAYNALD.

THE death of Cardinal Haynald, Archbishop of Kalocsa, is announced in the daily papers as having taken place on Saturday, the 4th inst. It was not an unexpected event, as his health had been gradually getting worse for some two or three years. Last year he celebrated the jubilee of his priesthood, and Dr. A. Kanitz, Professor of Botany in the University of Klausenburg, made it the occasion of publishing a eulogy on him as a botanist. This was translated into French by Prof. E. Martens, of Louvain. Although an excellent botanist, Cardinal Haynald was better known as a patron of botany than as a contributor to botanical literature. For the following particulars of his life and work we are mainly indebted to Dr. Kanitz's memoir.

Cardinal Haynald was born about 1816. His taste for botany was inherited from his father, who himself possessed a fine herbarium. During his stay at Vienna, in the Augustinæum, a theological college, he became acquainted with Edward Fenzl, then assistant curator of the botanical department of the Court, under whose tuition his botanical studies took a more practical shape. His priestly duties, however, did not allow him to follow his favourite study until he was appointed Bishop of Transylvania, when he began to investigate the flora of this country with indefatigable zeal. He became Archbishop of Karthago, and afterwards of Kalocsa, and after the accession of Leo the Tenth to the Papal chair, a Cardinal. He was a long time a prominent member of the Hungarian House of Magnates, and from 1873 also a member of the Royal Hungarian Academy of Science. Although always overburdened by the sacerdotal, political, and social duties of his high position, he found time to continue his botanical studies. He published only a few botanical papers, partly on Hungarian plants, and partly biographical sketches of botanists with whom he was more intimately acquainted, as Fenzl, Parlatore, and Boissier. His greatest merit, however, from a scientific point of view, was the assistance which he gave to botanical studies in Hungary by establishing a great private herbarium, which he placed in the most liberal way at anybody's disposal, and by the magnanimous generosity with which he always supported botanical enterprise, both in Hungary and abroad. The herbarium at his residence at Kalocsa was not only the richest in Hungary, but one of the largest private collections on the Continent. It was largely formed by the purchase of the herbaria of Heuffel, Schott, Kotschy, and Sodiro. Besides these and the plants collected by himself, he acquired most of the collections which have been distributed by subscription.

Hungary loses in Cardinal Haynald one of her greatest patriots, who was an honour to his profession, as well as to science, of which he was always a generous benefactor. Schur named after him a genus of grasses, founded on *Secale villosum*, Linn., which is reduced by Bentham and Hooker to Agropyrum, and Kanitz a genus of Lobeliaceæ.

OXFORD SUMMER MEETING OF UNIVERSITY EXTENSION STUDENTS.

THE process by which University Extension is carried throughout the country and made a vehicle for the further education of the adult student is well known, and is gradually becoming more and more appreciated in proportion as those who are responsible for the method improve the lines on which it is carried out. The machinery employed embraces lectures, classes, travelling libraries, &c., but one element vitally necessary to the University student is not supplied by these aids. This element is that of residence, and it was a happy suggestion on the part of the originators to propose that, for one month in the Long Vacation, arrangements should be made by which those who have profited by being brought into contact with a University lecturer should enjoy the additional advantage of being brought under the charm that haunts the colleges and cloisters of Oxford and Cambridge.

The Oxford summer meeting commences on July 31, and is continued throughout the month of August; but, for the benefit of students who are unable to be present during so long a period, the course is divided into two sections, the second commencing on August 12. It has been found desirable to remove as far as possible the fragmentary and isolated character of the lectures given at these meetings, and therefore, while the course will be complete and independent in itself, it will also form the first part of a cycle of study which for its full development will embrace a period of four summers.

That these lectures propose something more than to add piquancy to an agreeable picnic will be shown from the following slight sketch of the subjects treated—and treated by authorities of acknowledged reputation. To take the lectures on natural science first: in physiology, Mr. Poulton will discuss the recent criticisms of Weismann's theory of heredity, and Mr. Gotch will lecture on the functions of the heart. In chemistry, Prof. Odling lectures on the benzene ring, and under the supervision of Mr. Marsh a course of practical chemistry will be conducted in the laboratory of the University Museum. In geology, a course of practical instruction will be given by Prof. Green and Mr. Badger, to include excursions in the neighbourhood of Oxford. A class in practical astronomy will be welcomed at the University Observatory; while electricity finds an able exponent in Mr. G. J. Burch. But the distinguishing feature of this meeting is the attention given to agricultural science "designed for agricultural audiences under County Council schemes." This designation seems somewhat vague, and it will be very interesting to see the character of the audience attracted by this title. Four lectures are offered: the first is entitled, "The application of Science to the art of Agriculture." This description is sufficiently wide, but does not indicate whether the lecture is intended as a sample of those which State-aided Board

Digitized by Google

schools in agricultural districts might well offer to lads who have passed through the successive standards, or as one addressed to the sons of farmers, and supplying that form of instruction which it is the duty of agricultural colleges to impart. Another lecture is offered on the management of poultry. This is more definite and more hopeful; and when we remember that the students who come up for these summer meetings are, for the most part, ladies, who can well be supposed to take an intelligent interest in this part of farming operations, we must admit that the subject is well chosen. Manures of various characters form the subject of the other two lectures, and will be doubtless of a sufficiently technical character.

The literature and history lectures are of special interest, and by the combination of many lecturers are made to cover with great completeness the mediæval period. Mr. Frederic Harrison gives, as an inaugural lecture, a survey of the thirteenth century, and strikes the keynote of this section; while in the entire course, which embraces some sixty lectures, we meet the names of Prof. Dicey, of Mr. York Powell, of Mr. Boas, and a host of others, affording alike a sufficient guarantee for the excellence of the work, and a happy augury for the success of the meeting.

THE PROPOSED TEACHING UNIVERSITY FOR LONDON.

ON Monday, at the Council Office in Downing Street the Universities Committee of the Privy Council, consisting of the Lord President of the Council (Viscount Cranbrook), the Earl of Selborne, Lord Monk Bretton, Lord Basing, and Lord Sandford, reassembled for the purpose of giving their decision on the petition of King's and University Colleges for the grant of a charter for the establishment of a Teaching University for London.

The Earl of Selborne, in giving the opinion of their Lordships upon the draft charter of the proposed University, said, with regard to the opposition of the existing University of London, that some of the objections made might be treated as disallowed. It had been understood by their Lordships that a minimum course of two years' study at the new University would be required. If that was so, their Lordships were satisfied, and would say no more upon the point. The objections put forward by the medical faculty were generally disallowed. The word "London" would have to be omitted from the charter, but the University might be called either "the Albert University" or "the Metropolitan University." With regard to the suggestion that ten members of the Faculty of Medicine should be elected to the Council, their Lordships were of opinion that the medical schools should fill five places upon that body, or, if it were preferred, that each school should elect one member for the Medical Board of Study. If the Royal Colleges and the medical schools agreed to come in together, however, the number of members on the Council might be raised. Their Lordships did not approve of the proposed strength of the Council, and thought that four of the places might be accorded to the Faculty of Law. Teachers in any branch of science, their Lordships considered, should be admitted as members of the Science Faculty, and the six places on the Council which it was proposed to give to the Royal Colleges should be supplied according to the 29th paragraph of the Royal Commissioners' Report. If the medical schools and colleges declined to come in at first, provision ought to be made to allow them to do so in the future. Their Lordships thought that a place upon the Council might be given to the Apothecaries' Society, but they were not disposed to insist upon that being done. The view of their Lordships upon the question of honorary degrees was that no such degrees should be granted in medicine, and that the holding of an honorary degree should be no qualification for election to the Council. The ordinary degree in medicine should not be granted until the whole of the prescribed conditions had been fulfilled.

NOTES.

THE decision of the Universities Committee of the Privy Council with regard to the proposed new University for London is one that might have been expected from a body of non-experts. It is hasty, and will give satisfaction to no one by whom the subject has been seriously considered. It may throw back the higher teaching in London for half a century.

MR. WALTER BESANT, in an imaginary "Page from the Kaiser's Diary," notes that there are not to be seen at Court any of "the people who make the real greatness of the country—its traders, its manufacturers, its men of science, art, and literature." It has been remarked that in this respect the City Corporation, last Friday, followed the example of the Court, no representative of science, or literature, or art, as such, having been invited to the Guildhall banquet. It would have been better to follow the precedent set at the time of the Czar's visit, when a large number of the leading scientific men were asked to the reception at the Foreign Office, and were personally presented.

AT the ensuing British Association meeting at Cardiff, it is proposed to hold in Section A, if possible in conjunction with Section G, a discussion on "Units and their Nomenclature," having special regard to the new electrical and magnetic units now becoming necessary for practical purposes.

THE Secretary of State for India in Council has appointed, on the nomination of the Government of India, the following persons to represent it on the permanent governing body of the Imperial Institute, for the year ending April 30, 1892:—W. T. Thiselton-Dyer, C.M.G., F.R.S., Director, Royal Gardens, Kew; General James T. Walker, R.E., C.B., F.R.S., late Surveyor-General of India; John W. P. Muir-Mackenzie, Under-Secretary to the Government of India Revenue and Agricultural Department.

SIR J. D. HOOKER has been elected a Foreign Member of the Academy of Sciences in Buda-Pesth.

THE Secretary of State for the Colonies has appointed, on the nomination of Kew, Mr. C. A. Barber, late Scholar of Christ's College, Cambridge, and University Demonstrator in Botany, to be Superintendent of the recently created Agricultural Department of the Leeward Islands. The Superintendent will reside in Antigua, and will have the general supervision of the botanical stations at Antigua, Dominica, Montserrat, and St. Kitts-Nevis.

THE Council of University College, Liverpool, have appointed Mr. Francis Gotch, of Oxford, to their new Chair of Physiology.

THE Foreign Office has expressed the wish that the "Flora of Tropical Africa," prepared at Kew under the editorship of Prof. Oliver, and of which three volumes have appeared, should be continued and completed. It is calculated that four more volumes will be required, and the Treasury has sanctioned a scheme by which the necessary funds will be provided.

THE Accademia dei Lincei of Rome has awarded to Prof Saccardo, of Padua, in acknowledgment of his labours in mycology, the Royal prize of 10,000 francs intended for the encouragement of morphological researches.

THE Government has appointed the Council of the Society of Arts as a Royal Commission to direct the formation of the British Section at the Chicago Exhibition. If we may judge from the preparations which are being made in America, the Exhibition is likely to be one of great splendour. One of its attractions will be a collection of objects relating to ethnology and archæology. This is being organized by Prof. Putnam.

A COMMITTEE, as we recently stated, has been appointed for the reorganization of the Natural History Museum in Paris. By some who interest themselves in the question it is proposed that the Museum should be made the only institution in Paris for the study of natural history. According to this scheme, all natural history chairs in the Sorbonne and elsewhere would be suppressed, while all chairs in the Museum which do not belong to natural history proper would also disappear. The professors would have to examine all candidates in natural science.

A COMMITTEE appointed by the Photographic Society of Great Britain has presented a report on the proposal that the photographic societies of the United Kingdom should unite more closely for the better promotion of their common interests. The Committee advises that it should be open to photographic societies to affiliate themselves to the Photographic Society of Great Britain; and suggestions are made as to the way in which affiliation should be effected.

THE fifth session of the Edinburgh Vacation Courses will begin on August 3. M. Espinas, Professor of Philosophy and Dean of the Faculty of Letters in the University of Bordeaux, has been charged by his Government to report upon the educational scheme and methods of these courses, and also desires to inquire into Scottish higher education generally. Dr. H. de Varigny, who will deliver a series of lectures on general biology, is also to report to the French Government on the University Extension movement. The expected presence of these and other foreigners has suggested the idea that it might be well to hold, at Edinburgh, a small informal Congress, or rather a short series of meetings, for the discussion of curricula, higher educational methods, and other questions of immediate interest. Particulars on this subject will shortly be announced.

THE Royal Society of Antiquaries of Ireland hold their general meeting in the Town Hall, Killarney, on August 11. Excursions are planned for every day, except Sunday, from August 11 to 20.

THE Royal Archæological Institute will hold its annual meeting at Edinburgh from August 11 to 18. Sir Herbert Maxwell will preside.

THE German Anthropological Society will hold its twenty-second annual meeting at Danzig, from August 3 to 5.

HER MAJESTY'S Commissioners for the Exhibition of 1851, assisted by a committee of gentlemen experienced in scientific education, have made the following appointments to Science Scholarships for the year 1891. The scholars have been *bonâ-fide* students of science for at least three years, and were nominated for the Scholarships by the authorities of their respective Universities or Colleges. The Scholarships are of the value of £150 a year, and are tenable for two years (subject to a satisfactory report at the end of the first year) in any University at home or abroad, or in some other institution to be approved of by the Commissioners. The scholars are to devote themselves exclusively to study and research in some branch of science the extension of which is important to the industries of the country. A Scholarship was offered to the University of Sydney, but the Council found themselves unable to nominate a suitable candidate. Nominating institution—University of Edinburgh, scholar—John Shields, institution to which scholar proposes to attach himself—University of Edinburgh and a Continental University, probably Leipzig; University of Glasgow, James H. Gray (*a*), University of Glasgow; University of St. Andrews, William Frew, University of Munich; Mason Science College, Birmingham, John Joseph Sudborough, University of Heidelberg; University College, Bristol, Frederick Benjamin Fawcett (*a*), University College, Bristol; Durham College of Science, Newcastle-on-Tyne, William M'Connell, jun. (*a*), Durham College of Science; Yorkshire College, Leeds, Harry Ingle, a German University, probably Wurzburg; University College, Liverpool, Robert Holt (*a*), University College, Liverpool; Owens College, Manchester, Thomas Ewan, Owens College, first year; University College, Nottingham, Edwin H. Barton (*b*), South Kensington; Firth College, Sheffield, Annie J. Hoyles (*a*), Firth College, Sheffield; University College of South Wales and Monmouthshire, Franke Herbert Parker, first year same College, second year a German University; Queen's College, Belfast, Benjamin Moore, University of Leipzig; Royal College of Science for Ireland, Frederick William Dunn, first year University of Glasgow, second year Berlin; M'Gill University, Montreal, Percy Norton Evans, University of Berlin, and probably other German Universities; University of Melbourne, William Huey Steele (*a*), University of Melbourne. (*a*) These scholars have been recommended to spend part of the term of scholarship at some other institution. (*b*) This appointment is conditional on the candidate passing examination for B.Sc. London.

THOSE who require power for electric lighting may be interested to know that Messrs. Priestman Brothers have a good account to give of the success of their oil-engine. Many orders have been received for engines varying in size from 1 to 25 actual h.p. for electric lighting, and Messrs. Priestman, in order to meet the growing demand, have largely extended their works.

ACCORDING to a telegram sent through Reuter's Agency from San Francisco, July 11, an enormous cavern in Josephine County, Oregon, at a point twelve miles north of California and forty from the coast, has been discovered. It has two openings, and contains many passages of great beauty. There are numbers of semi-transparent stalactites, several giant milk-white pillars, and a number of pools and streams of clear, cool water. A week was spent in exploring the cavern, and innumerable passages and chambers were discovered. On penetrating one of these passages for a distance of several miles, the exploring party came across a lake of clear water and a waterfall thirty feet high. All kinds of grotesque figures were found in the various chambers; but the only signs of animal life were discovered a short distance from the entrance, where a few bones were found, indicating that bears had carried their prey there. The cavern appears to be fully as large as the Mammoth Cave in Kentucky.

DR. D. PRAIN, Curator of the Calcutta Herbarium, has published in the Journal of the Asiatic Society of Bengal, and separately, a memoir on new Indian *Labiatæ*. Nearly fifty species, belonging to upwards of twenty genera, are added to those described in the "Flora of British India." They are mostly from frontier extensions of the Empire, some from the east, some from the west; and nearly half of the species are new to science. Specially interesting among these is Prain's new genus *Microlæna*, founded upon the *Plectranthus Patchouli*, Clarke—a plant cultivated in Assam; and a second species, collected by Griffith, probably in Assam. The first has since been found wild in Muneypore, Burma, Tonkin, and South-Eastern China. Two very distinct species of the same genus have also been recently discovered by Dr. A. Henry, in Central China.

THE new "Flora of France," which is being prepared by Prof. G. Bonnier, with the assistance of a number of botanists,

Digitized by Google

will be published under the auspices of the Minister of Public Instruction of France.

The annual publication of the very useful "Correspondance botanique" ceased with the death of its editor, Prof. E. Morren, of Liége. With the aim of supplying its place, the International Library, 4 Rue de la Sorbonne, Paris, has now issued a "Nouvelle Correspondance botanique: liste des botanistes de tous les pays, et des établissements, sociétés, et journaux de botanique."

PRINCE ROLAND BONAPARTE has issued, at his own expense, a handsome book on Corsica, recording his travels and the history of the island. He also gives a full bibliography relating to the subject.

A NEW quarterly scientific journal has made its first appearance in Paris, under the title *Revue des Sciences naturelles de l'Ouest*, devoted to the interests of zoology, botany, geology, mineralogy, anthropology, embryology, and teratology.

A MONTHLY journal of natural science, which may have many opportunities of doing good work, has just been started in Malta. It is called *The Mediterranean Naturalist*, and is edited by Mr. John H. Cooke, F.G.S.

THE "Dictionnaire d'Agriculture," by J. A. Barral and H. Sagnier, will soon be completed. Vol. iv. is nearly ready, and will be quickly followed by Vol. v.

A NEW edition of the Great Eastern Railway Company's "Tourist Guide to the Continent," edited by Mr. Percy Lindley, has been published. New editions of Mr. Lindley's "Walks in the Ardennes" and "Walks in Epping Forest" have also been published; and he has compiled two other useful little hand-books, "Walks in Holland" and "Holidays in Belgium."

MESSRS. GUY AND CO., Cork, send us "Guy's South of Ireland Pictorial Guide," in which are described and illustrated much fine scenery and various things interesting to students of natural history and archæology.

MESSRS. DULAU AND CO. have issued a catalogue of the works on geology which they are offering for sale.

THE results of an investigation concerning the cause of the insolubility of pure metals in acids are contributed by Dr. Weeren to the current number of the *Berichte*. De la Rive, so long ago as the year 1830, pointed out that chemically pure zinc is almost perfectly insoluble in dilute sulphuric acid. Hitherto, however, the hypotheses put forward attempting to account for this singular fact have been anything but satisfactory. The theory of Dr. Weeren is extremely simple, and is fully supported by the most varied experiments, physical and chemical. It may be stated as follows: "Chemically pure zinc and also many other metals in a state of purity are insoluble or only very slightly soluble in acids, because, at the moment of their introduction into the acid, they become surrounded by an atmosphere of condensed hydrogen, which under normal circumstances effectually protects the metal from further attack on the part of the acid." It is found that when a piece of pure zinc is immersed in dilute sulphuric acid, a slight action does occur during the first few succeeding moments, zinc sulphate and free hydrogen being formed in minute quantity. The free hydrogen, however, instead of escaping, becomes condensed by the molecular action of the zinc upon the surface of the latter, and is retained there with great tenacity as a thin mantle of highly compressed hydrogen gas, capable of affording perfect protection against further inroad of the acid. The experiments from which this simple and very probable explanation has been derived were briefly as follows. The amount of chemically pure zinc dissolved by the acid was first determined. It was, of course, an exceedingly minute quantity. Considering this amount as unity, it was next sought to determine what difference would be effected by performing the experiment *in vacuo*, when of course the escape of the hydrogen would be greatly facilitated. The solubility was found under these circumstances to be increased sevenfold. Next the experiment was performed at the boiling temperature of the dilute acid, first when ebullition was prevented by increasing the pressure, and secondly when ebullition was unhindered, thus again facilitating the removal of the hydrogen film. In the first case, when ebullition was prevented, the solubility was practically the same as in the cold; while in the second case, with uninterrupted ebullition, the solubility was increased twenty-four times. Finally, experiments were made to ascertain the effect of introducing into the acid a small quantity of an oxidizing agent capable of converting the hydrogen film to water. When a little chromic acid was thus introduced the solubility was increased 175 times, and when hydrogen peroxide was employed the solubility was increased three-hundred-fold. The explanation of the ease with which the metal becomes attacked when the ordinary impurities are present is that the hydrogen is not then liberated upon the surface of the zinc, but rather upon the more electro-negative impurities, leaving the pure zinc itself open to the continued attack of the acid. The same of course occurs when a plate of platinum is placed in contact with a plate of pure zinc in the acid. The action of nitric acid, the only common acid which does attack pure metals, is evidently due to the oxidation of the hydrogen film by further quantities of the acid, with formation of water and production of the lower oxides of nitrogen, and even under certain circumstances of ammonia.

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus*) from India, presented by Mr. R. Armstrong; two Senegal Touracous (*Corythaix persa*) from West Africa, presented by Sir Brandforth Griffith, Bart.; two Rock Thrushes (*Monticola saxatilis*) from Italy, presented by the Rev. Hubert D. Astley; two Larger Hill-Mynahs (*Gracula intermedia*) from China, deposited; two Mule Deer (*Cariacus macrotis*), three Summer Ducks (*Æx sponsa*), seven Mandarin Ducks (*Æx galericulata*), five Chilian Pintails (*Dafila spinicauda*), two Australian Wild Ducks (*Anas superciliosa*), a Spotted-billed Duck (*Anas pœcilorhyncha*), three Night Herons (*Nycticorax griseus*), bred in the Gardens.

OUR ASTRONOMICAL COLUMN.

THE STELLAR CLUSTER χ PERSEI.—Mr. O. A. L. Pihl has completed a micrometric examination, begun in 1870, of the group χ of the great star cluster in Perseus, and the results are published by Grondahl and Son, Christiania. His survey includes all stars down to 10·6 magnitude, and a number of fainter ones down to 11·7 magnitude, the total number of stars measured being 236. The positions obtained, joined to those determined in the *b* group by Prof. Krüger, with the Bonn heliometer, form one continuous survey of both components of the cluster. Prof. Vogel has determined the positions of 178 stars in the central part of the χ group, but Mr. Pihl's investigation covers more than four times the area. A comparison of the right ascensions of the stars measured by these two observers brought to light differences of a systematic character which appeared to be neither the result of observational errors nor of calculation. Upon closely inspecting the measures, Mr. Pihl found that his value for right ascension was less than Prof. Vogel's in the case of those stars which were brighter than the star to which positions were referred; whereas for all stars fainter than this his value was larger, and the fainter the star the greater the difference.

A ring and a bar micrometer were used in the observations, and the reductions were made by the ordinary method of taking half the sum of the moments of ingress and egress in the calculation—a mode of proceeding which depends upon the supposition that the half sum denotes the instant of the passage of

Digitized by Google

the star through the middle of the ring or bar. This supposition, however, is shown to be erroneous. For stars of a less magnitude than 5·5 there is always a detention in the apparent time of emersion, which increases with the faintness of the stars observed. The cause of the error, therefore, is physiological, and due to the occulting micrometers employed. The law regulating it having been found, the necessary corrections have been applied to the measures, thus rendering the work of greater use.

The memoir represents the work of a business man over a period of twenty years, and with an instrument having an aperture of 3¼ inches. It contains much of interest, and will doubtless be appreciated as an important contribution to the knowledge of the stars in a cluster which is certainly one of the grandest of telescopic objects.

ON THE VEGETATION OF TIBET.

IN the May number of the *Journal de Botanique* MM. Bureau and Franchet describe a number of new plants from the collections recently brought home by M. Bonvalot and Prince Henry of Orleans, and give a general summary of their character, of which the following is an abstract:—

The collection was made almost entirely in a narrow band of territory reaching from Lhassa eastward near the 30th parallel of north latitude by way of Batang and Sitang to Tatsienlow, in the province of Szechwan, in West China, from which place their route was deflected at a right angle to Yunnan.

Considered in its general aspect, the flora of this region, as shown in the collection, is marked by the stunted form of the shrubs and dwarf character of the herbaceous vegetation. Of the forest trees, Coniferæ and others, no specimens were brought. It is characteristically a vegetation of high peaks, where drought and strong winds are the main climatic features. The Papaveraceæ are represented especially by dwarf, large-flowered kinds of *Meconopsis*. The greater number of the species of *Corydalis* are not more than two or three inches high. The Cruciferæ, such as *Parrya ciliaris*, in the same way are dwarf and large-flowered. *Silene cæspitosa* may be compared with the most dwarf states of *S. acaulis* of our own high mountains. The honeysuckle of Tibet constitutes only a small bush about a foot high, with intertangled branches. But it is especially in the Rhododendrons and Primulas that this dwarf character is remarkable. All the Rhododendrons and Primulas found between Lhassa and Sitang—*R. principis*, *R. primulæflorum*, *R. nigropunctatum*, *Primula leptopoda*, *P. diantha*, and *P. Henrici* may be ranged amongst the dwarfest types of the genera to which they belong. It is the same with *Incarvillea*. The Tibetan species belong to a group found also in Kansu and Central Yunnan, with stem almost obliterated and corolla very large.

Passing eastward in Szechwan the flora puts on a different character. The leaves become larger, the number of flowers to each plant increases. There are many Rosaceæ, Orchids, and species of Pedicularis; amongst the Compositæ the genus Senecio is particularly well represented, and there are several Everlastings that approach the Edelweiss of the Swiss Alps.

The flora of this eastern part of Tibet and western region of Szechwan has a strong affinity both with that of the Sikkim Himalaya and that of Central Yunnan. *Meconopsis Henrici* represents the Himalayan *M. simplicifolia*, Hook. et Thoms.; *Astragalus litargensis*, *A. acaulis*, Benth., *Rubus xanthocarpus*, *R. sikkimensis*; *Brachyactis chinensis*, *B. menthodora*; *Gnaphalium corymbosum* answers to *G. nubigenum*; *Androsace bisulca* to *A. microphylla*; and there are many other similar parallels between the plants of Tibet and Sikkim, and in the same many parallels may be found between the new species found by our travellers in Tibet and those gathered by Delavay in Yunnan.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, June 18.—"An Apparatus for testing the Sensitiveness of Safety-lamps." By Frank Clowes, D.Sc. Lond., Professor of Chemistry, University College, Nottingham. Communicated by Prof. Armstrong, F.R.S.

The following apparatus has been devised to render easy the process of testing the sensitiveness of different forms of safety-lamps when used for detecting firedamp. To enable satisfactory tests to be made in the laboratory, it was necessary to insure (1) the easy and rapid production of mixtures of firedamp and air in known proportions; (2) to insure economy of the artificially prepared methane, which represented firedamp; and (3) to examine the flame of the lamp under conditions as satisfactory as those existing in the mine.

A wooden cubical box of about 100 litres capacity was constructed so as to be as nearly gas-tight as possible. It was then made absolutely gas-tight by painting it over with melted paraffin wax, which was afterwards caused to penetrate more perfectly by passing an ordinary hot flat-iron over the surface.

FIG. 1.

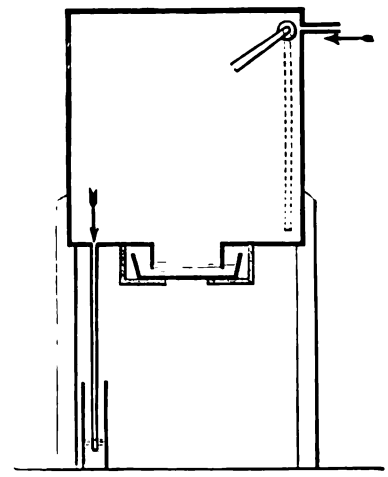

FIG. 2.

This testing chamber was furnished with a small inlet tube at the top, and with a similar outlet tube below. It had a plate-glass window in front for observing the lamp in the interior, and a flanged opening below for introducing the safety-lamp. This opening was closed by a water-seal consisting of a small zinc tray supported by buttons, and containing about 2 inches depth of water, into which the flange dipped. A mixer was arranged, which consisted of a light flat board, nearly equal in dimensions to the section of the chamber, and suspended by an axis from the upper corner of the chamber. The mixer was moved rapidly backwards and forwards from the side to the top of the interior of the chamber, by grasping a handle projecting through the front of the chamber.

When a mixture of air with a certain definite precentage of

Digitized by Google

firedamp was required, the methane, prepared and purified by ordinary chemical methods, was introduced into the chamber in the requisite quantity by the top inlet. It displaced an equal volume of air, which escaped through the lower outlet, the exit end of which was sealed by being immersed just beneath a water surface. A vigorous use of the mixer secured a uniform mixture of gas and air throughout the interior of the chamber in the course of a few seconds. The lamp was then introduced into the chamber, and placed in position behind the glass window. The simplicity of arrangement of the water-seal rendered the necessary opening of the chamber very brief, and the introduction and removal of the lamp many times in succession was not found to produce any appreciable effect upon the composition of the atmosphere inside the chamber. The appearance and dimensions of the "cap" over the flame were noted as soon as the cap underwent no further change. A lamp was left burning in the chamber for a considerable length of time, and its indications underwent no change, owing to the large capacity of the chamber and the very limited amount of air required to support the combustion of the small flame always used in gas-testing. The whole interior of the chamber and mixer were painted dead-black, so as to render visible pale and small caps against a black ground.

The methane was introduced from an ordinary gas-holder. A volume of water, equal to that of the methane to be displaced, was poured into the top of the gas-holder. The gas-tap of the holder was then momentarily opened, so as to produce equilibrium of pressure between the methane and the atmosphere. The gas-tap having then been placed in connection with the upper inlet of the chamber, the water-tap was opened, and the measured volume of water was allowed to flow down and drive the methane into the chamber. As soon as bubbles of air ceased to appear through the water at the outlet, the chamber was closed; the mixer was then vigorously worked for a few seconds, and the mixture of gas and air was ready for the introduction of the lamp. Before introducing the methane for a fresh mixture, the atmosphere of the chamber was replaced by fresh air by removing the water-tray from beneath the opening at the bottom of the chamber, and blowing in a powerful stream of air from a bellows to the top of the chamber.

The chamber was supported on legs, which were arranged so as to place it at a convenient height for observations through the window, and also for the introduction and removal of the safety-lamp.

The observations were usually made in a darkened room, but the flame-caps were easily seen in a lighted room, provided direct light falling on the eye or chamber was avoided.

The capacity of the chamber was 95,220 c.c.; accordingly, the following volumes of methane were introduced: for ½ per cent. mixture 476 c.c., for 1 per cent. 952 c.c., for 2 per cent. 1904 c.c., for 3 per cent. 2856 c.c., for 4 per cent. 3808 c.c., and for 5 per cent. 4760 c.c. It will be seen that a series of tests, in which the above-mentioned percentage mixtures were employed, involves an expenditure of only 15 litres of methane, a quantity far smaller than that required by any other method of testing as yet described.

Of many forms of safety-lamp tested in the above apparatus, the one which most satisfactorily fulfilled the two purposes of efficient illumination and delicacy in gas-testing was Ashworth's improved Hepplewhite-Gray lamp. This lamp is of special construction, burns benzoline from a sponge reservoir, and its flame is surrounded with a glass cylinder, which is ground rough at the hinder part; this latter device prevents the numerous reflected images of the flame, and the generally diffused reflections which are seen from a smooth glass surface, and which render the observation of a small pale flame-cap very difficult, if not impossible.

The wick of this lamp, when at a normal height, furnishes a flame of great illuminating power. When lowered by a fine screw adjustment the flame becomes blue and non-luminous, and does not interfere therefore with the easy observation of a pale cap. The following heights of flame-cap were observed, which fully bear out the unusual sensitiveness of this flame. With 0·5 per cent. of methane 7 mm.; with 1 per cent. 10 mm.; with 2 per cent. 14 mm.; with 3 per cent. 20 mm.; with 4 per cent. 25 mm.; and with 5 per cent. 30 mm. The cap, which with the lower proportions was somewhat ill-defined, became remarkably sharp and definite when 3 per cent. and upwards of methane was present. But even the lowest percentage gave a cap easily seen by an inexperienced observer.

It appears from the above record of tests that the problem of producing a lamp which shall serve both for efficient illuminating and for delicate gas-testing purposes has been solved. The solution is in some measure due to the substitution of benzoline for oil, since the flame of an oil-lamp cannot be altogether deprived of its yellow luminous tip, without serious risk of total extinction; and this faint luminosity is sufficient to prevent pale caps from being seen.

From further experiments made in the above testing-chamber with flames produced by alcohol and by hydrogen, it was found to be true in practice, as might be inferred from theory, that, if the flame was pale and practically non-luminous, the size and definition of the flame-cap was augmented by increasing either the size or the temperature of the flame. It is quite possible by attending to these conditions to obtain a flame which, although it is very sensitive for low percentages of gas, becomes unsuitable for the measurement of any proportion of gas exceeding 3 per cent. This must, for the general purposes of the miner, be looked upon as a defect; but it is not a fault of the lamp already referred to. It is of interest to note that with the Pieler spirit-lamp a flame-cap an inch in height was seen in air containing only 0·5 per cent. of methane.

Physical Society, June 26.—Prof. W. E. Ayrton, F.R.S., President, in the chair.—The following communications were made:—The construction of non-inductive resistances, by Prof. W. E. Ayrton, F.R.S., and Mr. T. Mather. In making some transformer tests about three years ago, the authors had occasion to consider the construction of electric conductors the impedances of which should be practically equal to their resistances. This condition could only be fulfilled by making the inductance small in comparison with the resistance; and, as the former does not depend on the material employed (excepting iron) it was important to use substances of high specific resistance. Carbon or platinoid being available, the latter was chosen on account of its low temperature coefficient. One form of resistance exhibited consisted of strips of thin sheet platinoid about 6 metres long and 4 centimetres wide. Each was bent at the middle and doubled back on itself, thin silk being placed between the contiguous parts and narrow ribbon used to bind the parts together. Twelve such strips arranged in series had a resistance of 2·95 ohms, and would carry a current of 15 amperes without changing its resistance more than $\frac{1}{10}$ per cent. This strip-resistance was made by Messrs. C. G. Lamb and E. W. Smith, who at that time (1888) were students in the Central Institution, and to whom the author's best thanks are due for the praiseworthy manner in which they surmounted the difficulties which presented themselves. Another form of resistance designed for portability consisted of bare-wire spirals, each length having a left-handed spiral placed within a right-handed one of slightly larger diameter, and the two being connected in parallel. This device was found to reduce the inductance to $\frac{1}{10}$ or $\frac{1}{50}$ of that of a single spiral according as the diameters of the spirals approach towards equality. Where the spirals are made of platinoid wire, the ratio of inductance to resistance is very small, averaging about $\frac{1}{100}$ to $\frac{1}{600}$.—On the influence of surface loading on the flexure of beams, by Prof. C. A. Carus-Wilson. Referring to the practical treatment of problems on beam flexure as based on Bernoulli's hypothesis that the bending moment is proportional to the curvature, the author pointed out that this assumes that the cross-sections remain plane after flexure, and neglects the surface loading effect. The present paper describes experiments made to determine the actual state of strain in a beam doubly supported, and carrying a single load at the centre, the effect of surface loading being taken into account. The method of investigation assumes that (1) the true state of strain at the centre of a beam may be found by superposing on the state of strain due to bending only, that due to surface loading without bending; (2) the state of strain due to surface loading only, may be found with close approximation to truth by resting the beam on a flat plane instead of on two supports; (3) the strain due to bending alone, may be obtained from the Bernoulli-Saint-Venant results. Before proceeding to describe the experiments, a short account of the mathematical work previously done on the subject was given. The nearest approach to the particular case here dealt with had been worked out by Prof. Boussinesq, who had shown that for an infinite elastic solid bounded on one side by a plane surface and loaded along a line on that surface, the stress (y) on an element on the normal through the middle point of the line varies inversely as its dis-

Digitized by Google

tance (x) from the surface. The formula thus arrived at was $y = 0{\cdot}64\frac{P}{x}$, whilst for a finite beam centrally loaded the author's experiments gave $y = 0{\cdot}726\frac{P}{x}$. The experiments were made on glass beams mounted in a steel straining frame, and placed between the crossed Nicols of a polariscope. Steel rollers 2 mm. in diameter served as supports, and the central load was applied by a screw acting on a roller of similar diameter. Deflections of the beam were measured by a micrometer screw at a point opposite the central load, and traversing screws enabled the whole frame to be moved so as to bring any portion of the beam in the field of view. Circularly polarized light was sometimes used, and a micrometer eye-piece served to measure the distances between interference fringes produced by loading. By carefully chosen experiments the author had shown that if a beam of glass be laid on a flat surface and loaded across its upper surface, the shear at any point on the normal at the point of contact of the load is inversely proportional to the distance from the point of contact. In the first experiment the crossed Nicols were set at 45° to the axis of the loaded bar; a quarter-wave plate was then placed between the bar and the analyzer, and the position of the black spot at the point where the effect of the shear on the polarized light was equal and opposite to that produced by the quarter-wave plate was noted. A second quarter-wave plate was then superposed on the first; the black spot moved upwards to a point where the shear was double that at the first position. This position having been determined, one quarter-wave plate was removed, and the load diminished until the original spot moved up to the second position, and the processes repeated. By this means a series of positions at which the shears were in the proportions 1, 2, 4, 8, &c., were determined. Plotting the results showed the curve connecting the shear and the distance from the point of contact to be hyperbolic. Other experiments showed that the shear at any point was proportional to the load. By maintaining a constant load and measuring the distances between the interference fringes below the point of contact the hyperbolic law was confirmed. The effect of bending a beam is, according to hypothesis, to put the upper portion in longitudinal compression, and the shear (vertical stretch) varies as the distance from the centre of the beam; the shear due to surface loading is a vertical squeeze, and, as shown above, varies hyperbolically. When, therefore, the beam is subjected to both actions, the straight line representing the bending strain may intersect the hyperbola representing the shear due to surface loading in two points, and since, at the corresponding points in the central section, the shears are equal and opposite, the elements are only subjected to voluminal compression, and will exert no bi-refringent action. Hence, when viewed through crossed Nicols, black spots will be seen on a white field. Keeping the load constant and diminishing the span should cause the spots to approach each other, and when the line is tangential to the hyperbola, the spots coincide. These deductions were confirmed by experiment, and it was found that for a span of less than four depths, no point of zero shear exists on the central section. The strains in beams subjected to surface loading were thus shown to be of a character different from those usually assumed, the neutral axis instead of coinciding with the axis of the beam, being lifted up in the centre, and its shape depending on the load and span. Other ingenious and interesting experiments on beams were described, in some of which the lines of principal stress were mapped out. Remarkable results were obtained, showing that although the tension lines given by Rankine and Airy are nearly correct, the curves of compression may be very different, and have very curious shapes. Prof. Perry thought the local loading effect would not be so important in long beams, and inquired whether in ordinary test pieces local loading would affect the breaking strength. He also asked what effect the fact of the load making contact over a surface instead of along a line would have on the results, and in reply Prof. Carus-Wilson said the effect was to raise the asymptote of the hyperbola representing the surface loading stress above the surface of the beam.—On pocket electrometers, by C. V. Boys, F.R.S. This communication described modifications of electrometers adapted for portability. As quartz fibres increase the delicacy and diminish the disturbing influences affecting instruments, much smaller controlling forces can be employed than when silk is used for suspensions. He had, he said, pointed out some time ago the great advantages arising from making galvanometers small. Applying similar reasoning to electrometers, he remarked that making an instrument one-tenth the size of an existing one reduced the moment of inertia of the needle to $\frac{1}{10^5}$, whilst the deflecting couple for given potentials would only be $\frac{1}{10}$ of its former value. The small instrument would for the same periodic time be 10,000 times more sensitive than the large one, provided the disturbing influence could be reduced in the same proportion. This, however, was not ordinarily possible, for any method of making contact with the needle, such as by a fine wire dipping into acid or mercury, prevented very small controlling forces being used. Still, by suitable devices a large proportion of the full advantage could be obtained; a freely suspended needle without liquid contacts was essential to success. The first instrument described was one in which the needle was cylindrical, contiguous quarters being insulated and connected to the opposite ends of a minute dry pile placed within the needle; opposite quarters were thus at the same potential, and at a different potential to the other pair of quarter cylinders. This was suspended within a glass tube silvered on the inside and divided into four parts by fine longitudinal lines. In such an instrument the needle and quadrants are reciprocal, and the deflection depends on the product of the difference of potential between the quadrants and that between the parts of the needle. Owing to the dry pile not being constant, the instrument was found untrustworthy, but when working at its best a Grove cell would give 30 or 40 millimetres deflection. The next step was to make a cross-shaped needle of zinc and platinum, and rely on contact electricity to keep the parts of the needle at different potentials. This bold experiment proved remarkably successful, for the instrument was very sensitive. A disk-shaped needle with quadrants, alternately zinc and platinum, was then employed, and by this a small fraction of a volt could be measured. The weight of the disk was only $\frac{1}{10}$ of a gramme, and the instrument could be turned upside down or carried about in the pocket with impunity. Another small instrument with the stationary quadrants of zinc and copper was exhibited, and by rotating them through an angle of 90°, so as to bring them in a different position relative to the parts of the needle, a deflection of several degrees of arc was produced. In the course of his remarks Mr. Boys made several suggestions relating to ballistic electrometers and electrostatic Siemens dynanometers, and pointed out the possibility of instruments such as he had exhibited being of use in elucidating the obscure points in connection with so-called "contact electricity." The President complimented Mr. Boys on the beautifully simple and remarkably sensitive electrometers exhibited. He remembered that some years ago Mr. Gordon made a very small electrometer, but its insulation was insufficient for electrostatic work. He agreed with Mr. Boys as to the advantages of small instruments, providing sparking across or tilting of the needle could be prevented. On the other hand, he thought the use of small potential differences on the needle was a step in the wrong direction, when great sensibility was required. Prof. Perry asked if the needle could not be kept charged by occasional contacts with a charged acid cup. Mr. Boys said he had originally intended using a fairly highly charged needle, but had not yet done so. He also suggested that an electrometer of very small capacity might be made by reducing the quadrants surrounding a disk-needle, until they became like small tuning-forks.—A paper on electrification due to the contact of gases with liquids, by Mr. J. Enright, and one on the expansion of chlorine by heat, by Dr. Arthur Richardson, were taken as read.

Entomological Society, July 1.—Mr. Frederick DuCane-Godman, F.R.S., President, in the chair.—Mr. Jacoby exhibited a specimen of a species of Coleoptera belonging to the family *Galerucidæ*, with the maxillary palpi extraordinarily developed.—Canon Fowler, on behalf of Mr. Wroughton, Conservator of Forests, Poona, exhibited specimens of a bug imitating an ant, *Polyrachis spiniger*, and of a spider imitating a species of *Mutilla*, and read the following notes:—"I have taken a good many specimens of a bug which has achieved a very fair imitation of *Polyrachis spiniger* (under the same stone with which it may be found), even to the extent of evolving a pedicle and spines in what, were it an ant, would be its metanotum. Curiously enough, however, these spines are apparently not alike in any two specimens. Is it that this bug is still waiting for one of its race to accidentally sport spines more like those of

P. spiniger, and thus to set the ball of evolution rolling afresh? or is it that the present rough copy of *spiniger's* spines is found sufficient to deceive? The bug has also been found in the Nilgherries. Mr. Rothney remarks on the above species:—'I have not found the species mimicking *Mutilla*; but in Calcutta and Barrackpore, where *P. spiniger* is a tree ant, forming its nest by spinning together the twigs of a shrub, the mimicking bug also assumes arboreal habits, and may be found on the trunks of trees with the ants.'"—Mr. Porritt exhibited living specimens of *Eupithecia extensaria* and *Geometra smaragdaria*: the position assumed by the former proved conclusively that it had rightly been placed in the genus *Eupithecia*.—Mr. Crowley exhibited two specimens of a *Papilio* from the Khasia Hills, belonging to an undescribed species allied to *P. papone*, subgeneric section *Chilades*. Colonel Swinhoe remarked that he possessed a specimen from Northern Burmah. Mr. Moore and others took part in the discussion which followed.—Mr. Dallas Beeching exhibited a specimen of *Plusia moneta*, recently taken by himself at High Woods, Tonbridge, and specimens of *Gonepteryx cleopatra*, lent him for exhibition, which were alleged to have come from the same locality.—Dr. Algernon Chapman exhibited the larva of *Micropteryx calthella*, and read notes on them.—Colonel Swinhoe read a paper entitled "On New Species of Heterocera from the Khasia Hills."—Mr. Crowley read a paper entitled "On a New Species of *Prothoe*."—Mr. C. J. Gahan read a paper entitled "On the South American species of *Diabrotica*, Part 2," being a continuation of Dr. Baly's paper on the same genus published in the Society's Transactions for 1890, Part 1.—Mr. W. F. Kirby communicated a paper entitled "Notes on the Orthopterous family *Mecopodidæ*."—Prof. Westwood communicated a paper entitled "Notes on *Siphonophora artocarpi*."

EDINBURGH.

Royal Society, June 15.—Mr. T. B. Sprague in the chair.—Dr. Johnson Symington and Dr. H. A. Thomson communicated a paper on a case of defective endochondral ossification in a human fœtus.—Dr. J. Berry Haycraft read a paper on the alkaline and acid salts of the blood and urine, and especially those of phosphoric acid.—Dr. J. M. Macfarlane presented the second part of a paper on the structure, division, and history of vegetable and animal cells, in which he stated that as a result of extended observation he still adhered to the view that a typical cell consists of protoplasm, nucleus, nucleolus, and endonucleolus, the whole usually surrounded by a cell wall; that the nucleolus is the important part equally in division and in sexual union of cells; that after division had ceased, successive fragmentation of endonucleolus, nucleolus, and nucleus occurred, though to a varying degree in different cells; that thus a multi-endonucleolar was followed by a multinucleolar, and this by a multinuclear state. He regarded the nucleolus of every cell as the sexual centre directly derived from union of the chromatic substance of the male and female pronuclei of the ovum, and that from the nucleolus extremely fine radiating threads of chromatic substance passed out along the achromatic fibrils, which last he viewed as a finely differentiated reticulum of the ground protoplasm. By union of the radiating chromatic threads, the author considered that the nuclear membrane was formed, while continuations radiated outwards from this through the cell-protoplasm to convey stimuli to and from the sex-centre or nucleolus. He further stated that many facts and direct observations made tended to show that the radiating threads from the nucleus, and ultimately therefore from the nucleolus, of one cell are connected with corresponding ones from other cells, and this, if fully verified, would cause us to regard an organism as a sexual whole, and the male and female reproductive cells as being specially set aside to hand down hereditary and acquired conditions. He showed that this had a special bearing on the next communication submitted—a comparison of the minute structure of plant hybrids with that of their parents, and its bearing on biological problems. At a previous meeting of the Society (May 4) he directly demonstrated, by three parallel lantern exhibitions of micro-photographs, that the tissues of root, stem, leaf, and flower parts in the hybrid named by Dr. Masters *Philageria Veitchii*, are exactly intermediate, when of corresponding age, between those of the parents; and further, that when a structure is developed in one parent, but is absent in the other—*e.g.* the sepal honey gland of *Lapageria*—the hybrid shows it of half the size. He now referred to eleven other hybrids whose tissues he had worked over in detail, and selected points from about sixty others, examined more or less minutely. By triplets of micro-photographs the author not only demonstrated that a hybrid is, to its minutest details, a blended reproduction of both parents, but that where the parents show diverse morphological details, these may be handed down to the hybrid of half the size, or one only may be inherited. He advanced a theory to explain this, and then compared the tissues of *Cytisus Adami* (see also *Gard. Chron.*, July 1890, p. 94), which he regarded as a true graft hybrid. He concluded by referring to the colour, flowering period, and constitutional vigour of plant hybrids, and to the light shed by these inquiries on the effects of environment, on the influence of sex, and on heredity.—Prof. Tait communicated paper, by Prof. Stokes, on an optical proof of the existence of suspended matter in flames. The method consists in condensing sunlight on the flame. The light is scattered by the solid particles in an extremely thin layer both where the beam enters the flame and where it leaves it. It is polarized in the plane of reflection. The effect is not found in some flames—such as a Bunsen flame tinged with burning sodium. In the latter case this seems to be due to the fact that the sodium is in the form of vapour—not of solid particles.

SYDNEY.

Royal Society of New South Wales, May 6.—Annua Meeting.—Dr. A. Leibius, President, in the chair.—The Report stated that 25 new members had been elected during the year, and the total number on the roll on April 30 was 457. During the year the Society held eight meetings, at which the following papers were read:—Presidential address, by Prof. Liversidge, F.R.S.—On a compressed-air flying machine, by L. Hargrave.—On the treatment of slips on the Illawarra Railway at Stanwell Park, by W. Shellshear.—On native names of some of the runs, &c., in the Lachlan district, by F. B. W. Woolrych.—Remarks on a new plant rich in tannin, by Charles Moore.—Record of hitherto undescribed plants from Arnheim's Land, by Baron Ferd. von Mueller, F.R.S.—The theory of the repetition of angular measures with theodolites, by G. H. Knibbs.—On some photographs of the Milky Way recently taken at Sydney Observatory, by H. C. Russell, F.R.S.—Australian aborigines: varieties of food and methods of obtaining it, by W. T. Wyndham.—On the application of the results of testing Australian timbers to the design and construction of timber structures, by Prof. Warren.—Geological notes on the Barrier Ranges silver-field, by C. W. Marsh.—Some folk-songs and myths from Samoa, by the Rev. T. Powell and Rev. G. Pratt, with an introduction and notes by Dr. John Fraser.—The coal-fields of New South Wales and their associated eruptive rocks, by T. W. E. David.—Some remarks on the Australian languages, by Dr. John Fraser.—On the 74-ounce compressed-air flying machine, by L. Hargrave.—The Medical Section held seven meetings, at which nine papers were read; the Microscopical Section held seven meetings, at which interesting exhibits were shown.—The Clarke Medal for the year 1891 had been awarded to Prof. F. W. Hutton, Canterbury College, Christ Church, New Zealand.—The Council had issued the following list of subjects with the offer of the Society's bronze medal and a prize of £25 for each of the best researches if of sufficient merit:—(To be sent in not later than May 1, 1892) On the iron-ore deposits of New South Wales; on the effect which settlement in Australia has produced upon indigenous vegetation, especially the depasturing of sheep and cattle; on the coals and coal measures of Australasia. (To be sent in not later than May 1, 1893) Upon the weapons, utensils, and manufactures of the aborigines of Australia and Tasmania; on the effect of the Australian climate upon the physical development of the Australian-born population; on the injuries occasioned by insect pests upon introduced trees.—A most successful *conversasione* had been held in the Great Hall of the University on December 10, at which 800 guests were present.—The Chairman read the Presidential Address, and the officers and Council were elected for the ensuing year, Mr. H. C. Russell, F.R.S., Government Astronomer, being President.

PARIS.

Academy of Sciences, July 6.—M. Duchartre in the chair.—On the lunar inequality of long period due to the action of Venus, and depending upon the argument $l + 16l' - 8l''$, by M. F. Tisserand. According to Delaunay, in calculations of this inequality it is possible to neglect powers of the inclination of the orbit of Venus higher than the second. M. Tisserand shows, however, that terms which contain the fourth power of the

Digitized by Google

inclination may have a sensible influence, and diminish the coefficient of the inequality in question by a tenth of its value—that is, by about 1″·6.—On the manner in which the velocities are distributed from the entrance of a cylindrical tube of circular section widened at the mouth up to the points where uniformity is established, by M. J. Boussinesq.—The flight of insects studied by photochronography, by M. Marey. The author describes an apparatus which he has used to obtain photographs of flying insects. It allows exposures to be made so short as $\frac{1}{1000}$ of a second. His observations indicate that the wings of insects in flight, by meeting obliquely the resistance of the air in to-and-fro movements, act in a very similar manner to the sculls used to propel rowing-boats.—Study of the tetra-iodide of carbon, by M. Henri Moissan. By acting on carbon tetrachloride with boron tri-iodide, the trichloride of boron and the tetra-iodide of carbon are obtained by double decomposition. A detailed account is given of this reaction. The carbon tetra-iodide thus prepared forms comparatively large crystals of a beautiful red colour, very similar to the rubies synthetically prepared by MM. Fremy and Verneuil. Several new reactions with this compound are described.—Compounds of camphors with the aldehydes: on a new mode of formation of alkyl camphors, by M. A. Haller.—The Eocene formations of Algeria, by MM. Pomel and Ficheur. It has been previously shown that the Eocene formations of Algeria may be divided into the three groups, lower, middle, and upper. The observations now stated indicate that the Middle Eocene formations only extend over a narrow zone, and that they are characterized by Nummulites of the groups *Numm. lævigata* and *Numm. perforata*. The Lower Eocenes are defined from a nummulitic point of view by *Numm. planulata*, *Numm. biarritzensis*, and *Numm. gizehensis*.—Method of ready transformation of the tubercular products of joints and certain other parts of the human body, by M. Lannelongue.—On the determination of the constants and coefficients of elasticity of nickel-steel, by M. E. Mercadier. Experiments have been made to determine the relation $\frac{\lambda}{\mu}$ for solid sonorous bodies, and, therefore, the coefficient of dynamical elasticity, by a method founded on Kirchhoff's theory of vibration of circular disks. From the results obtained it appears that the incorporation of a sufficient quantity of nickel with steel tends to make the alloy isotropic. The mean coefficient of dynamical elasticity for alloys containing about 5 per cent. and 25 per cent. of nickel is 18,600, whereas that of pure steel is 20,700.—Calculation of molecular volume, by M. G. Hinrichs.—On an explosive compound which results from the action of baryta water on chromic acid in the presence of oxygenated water, by M. E. Péchard. By adding baryta water in the presence of an excess of oxygenated water, a precipitate is produced, which, after desiccation, explodes violently by heat or percussion. The compound has the formula $BaO_3 . CrO_3$.—On the detection of small quantities of boric acid, by M. F. Parmentier.—On the structure of the ocellates of *Lithobius forficatus*, by M. Victor Willem.—Comparative study of the development and morphology of the parapodia of Syllidiæ, by M. A. Malaquin.

GÖTTINGEN.

Royal Society of Sciences.—The Proceedings of the Society for February, March, and May 1891 contain the following papers of scientific interest:—

No. 1.—W. Nernst: on Henry's law of chemical equilibrium in solutions.—F. Meyer: on discriminants and resultants of singularity-equations.—O. Venske: contribution to the integration of the equation $\Delta^2 u = 0$ for certain plane figures (the disk, the annulus, the rectilineal angle, the rectilinear strip with parallel sides, the annular sector).

No. 2.—W. Voigt: contributions to hydrodynamics (pulsating sphere or cylinder in an infinite liquid; stationary waves in a stream as an example of Kirchhoff's theory of liquid stream-rays; successive approximation to the irrotational motion of a heavy liquid with free surface; stationary combined motions depending on two co-ordinates in a liquid under a conservative system of forces; non-stationary current-motion, partly rotational, partly irrotational, within an ellipsoidal shell at rest).—O. Venske: integration of a special system of linear homogeneous differential equations, with doubly periodic functions as coefficients.—F. Meyer: on real properties of curves in space.

No. 3.—G. Tammann: on conduction through membrane-like precipitates.—O. Venske: a new apparatus for the determination in absolute measure of the internal thermal conductivity of badly conducting bodies.

STOCKHOLM.

MACMILLAN & CO.'S NEW SCIENTIFIC BOOKS.

NEW VOLUMES OF MACMILLAN'S MANUALS FOR STUDENTS.

A NEW TEXT-BOOK OF CRYSTALLOGRAPHY.

Crown 8vo, Cloth, 6s.

ELEMENTS OF CRYSTALLOGRAPHY FOR STUDENTS OF CHEMISTRY, PHYSICS, AND MINERALOGY. By GEORGE HUNTINGDON WILLIAMS, Ph.D., Assistant Professor in the Johns Hopkins University.

**** *A concise and elementary statement of the general principles of Crystallography, not intended as a complete treatise, but to furnish so much information on the subject as may be of service to students of other but allied branches.*

NATURE:—"We feel assured that the simultaneous publication in this country and in America of so simple and at the same time so accurate a text-book of the subject as the work we are now considering will do much towards reviving and diffusing a taste for the study of crystallography. The student who masters the contents of this little book will undoubtedly have much more to learn before he is competent to deal with all the higher problems of crystallographic science; but, however far his researches may be carried in the future—and this is, perhaps, the very highest praise we can give to the book—he will certainly have little, if anything, to *un*learn."

Crown 8vo, Cloth, 10s. 6d.

LESSONS IN ELEMENTARY BIOLOGY. By T. JEFFREY PARKER, B.Sc., F.R.S., Professor of Biology in the University of Otago, Dunedin, New Zealand. Illustrated.

NEW EDITION, REVISED.

Crown 8vo, Cloth, 10s. 6d.

A COURSE OF PRACTICAL INSTRUCTION IN BOTANY. By F. O. BOWER, D.Sc., F.R.S., Regius Professor of Botany, Glasgow.

NATURE:—"Everyone perusing the volume must be impressed with the high standard of its educational value. Teacher and student in this country are alike to be congratulated upon its publication."

ACADEMY:—"The work is one which should be in the hands of every practical botanist."

SATURDAY REVIEW:—"The types are good, easily obtained, and thoroughly worked out. . . . There is no padding, the text is to the point, and it assumes the presence of the plant concerned and the instruments in hand. We regard the absence of illustrations and of descriptive padding as important preventives of cram, and it should be clearly borne in mind that laboratory teaching suffers especially by the opening up of royal roads."

NEW VOLUME OF SIR WILLIAM THOMSON'S POPULAR LECTURES.

Crown 8vo, Cloth, 7s. 6d.

PAPERS ON NAVIGATION. By Sir WILLIAM THOMSON, LL.D., P.R.S., F.R.S.E., &c., Professor of Natural Philosophy in the University of Glasgow, and Fellow of St. Peter's College, Cambridge. [*Popular Lectures and Addresses*, Vol. III.

**** *The papers on navigation treat of such subjects as pilotage, astronomical navigation, "dead reckoning" or "account," deep-sea surroundings. In the papers relating to the tides, besides the general facts, the subjects of gravitation, the influence of the Straits of Dover on the tides of the British Channel and the North Sea, the tides of the southern hemisphere and the Mediterranean, the sketch proposed plan of procedure in tidal observation, and analysis and the equilibrium theory of the tides, are discussed and dealt with.*

NEW EDITION OF VOL. I.

New and Revised Edition, Crown 8vo, Cloth, 7s. 6d.

THE CONSTITUTION OF MATTER. By Sir WILLIAM THOMSON, LL.D., P.R.S. With Illustrations. [*Popular Lectures and Addresses*, Vol. I.

WITH PREFACE BY DR. A. R. WALLACE.

8vo, Cloth, 14s. net.

THE HISTORY OF HUMAN MARRIAGE. By EDWARD WESTERMARCK, Ph.D., Lecturer on Sociology at the University of Helsingfors.

I have seldom read a more thorough or a more philosophic discussion of some of the most difficult, and at the same time interesting, problems of anthropology. . . . On some points Mr. Westermarck has arrived at different and sometimes diametrically opposite conclusions from those of Darwin, Spencer, Morgan, Tylor, Lubbock, and he has done so after a most complete and painstaking investigation of all the available facts.

With such an array of authority on the one side and a hitherto unknown student on the other, it will certainly be thought that all the probabilities are against the latter. Yet I venture to anticipate that the verdict of independent thinkers will, on most of these disputed points, be in favour of the new comer who has so boldly challenged the conclusions of some of our most esteemed writers. Even those whose views are here opposed will, I think, acknowledge that Mr. Westermarck is a careful investigator and an acute reasoner, and that his arguments, as well as his conclusions, are worthy of the most careful consideration.

Every reader of the work will admire its clearness of style and the wonderful command of what is to the author a foreign language.—From Dr. WALLACE'S Preface.

TIMES:—"Very learned and elaborate, scientifically conceived and scientifically executed. It should command the serious attention of all scientific students of sociology."

NEW PART OF MR. BUCKTON'S MONOGRAPH OF THE CICADÆ.

Now Ready, Part VI., 8vo, Paper Covers, 8s. net.

MONOGRAPH OF THE BRITISH CICADÆ OR TETTIGIDÆ. Illustrated by more than Four Hundred Coloured Drawings, by GEORGE BOWDLER BUCKTON, F.R.S.

MESSRS. MACMILLAN & CO.'S PUBLICATIONS.

BY SIR ARCHIBALD GEIKIE, LL.D., F.R.S.

New and Revised Edition. Globe 8vo, 3s. 6d.

OUTLINES OF FIELD GEOLOGY. By Sir ARCHIBALD GEIKIE, LL.D., F.R.S., Director-General of the Geological Survey of Great Britain and Ireland.

"This volume has now been thoroughly revised and considerably enlarged. One of the chief changes will be found in the account of the schistose rocks, which has been re-written in the light of recent researches into these interesting but difficult parts of the geological record. A number of new illustrations have been added from my note-books."—From the Author's Preface.

BIRMINGHAM DAILY GAZETTE:—"In truth the book is as complete as care and experience can make it, and to every geological student its value is inestimable."

SCOTSMAN:—"Prof. Geikie condenses for the advantage of the student the results of many years' practice and experience in actual geological research. The utility of the book is enhanced by numerous diagrams and woodcuts."

GLASGOW HERALD:—"We can still more heartily recommend this book to all who wish to gain a practical knowledge of geological work in quarry or cutting, on mountain, in glen, or open country. The woodcuts are beautiful, and illustrate the text admirably."

HARDWICKE'S SCIENCE GOSSIP:—"A small volume ably and clearly written, and which cannot fail to take its place as one of the best introductions to the study of geology."

NORTH BRITISH DAILY MAIL:—"This clever little volume will be highly appreciated. Prof. Geikie has supplied what has long been felt to be a great want. The numerous illustrations and diagrams will be found to be of the very greatest assistance to the practical student."

NEW EDITION OF SIR J. W. DAWSON'S ACADIAN GEOLOGY.

Just Published, Fourth Edition, Royal 8vo, Cloth, 21s.

THE GEOLOGY OF NOVA SCOTIA, NEW BRUNSWICK, AND PRINCE EDWARD ISLAND, or ACADIAN GEOLOGY. By Sir J. WILLIAM DAWSON, LL.D., F.R.S., F.G.S., Principal and Vice-Chancellor of McGill College and University, Montreal. Fourth Edition, with Map, Illustrations, and 2 Supplements.

NEW AND REVISED EDITION OF AIRY'S POPULAR ASTRONOMY.

Just Published, Seventh Edition, Fcap. 8vo, 4s. 6d.

POPULAR ASTRONOMY: a Series of Lectures delivered at Ipswich by Sir GEORGE BIDDELL AIRY, K.C.B., late Astronomer-Royal. Revised by H. H. TURNER, M.A., B.Sc., Chief Assistant, Royal Observatory, Greenwich.

This edition has been very carefully revised by the Chief Assistant of the Royal Observatory, Greenwich, who has, however, introduced no more changes than were absolutely necessary to bring so well-established a book up to date.

BOOKS FOR CHEMICAL STUDENTS.

AUTHORIZED ENGLISH TRANSLATION OF MEYER'S HISTORY OF CHEMISTRY.

8vo, Cloth, 14s. net.

A HISTORY OF CHEMISTRY FROM THE EARLIEST TIMES TO THE PRESENT DAY. Being also an Introduction to the Study of the Science. By ERNST VON MEYER, Ph.D., Professor of Chemistry in the University of Leipzig. Translated with the Author's sanction by GEORGE MCGOWAN, Ph.D., Demonstrator in Chemistry, University College, North Wales, Bangor.

SPEAKER:—"A standard book on the subject. The conclusions are obviously the outcome of wide knowledge, independent research, and sound judgment."

SCOTSMAN:—"The book is an admirable one in every way. Beginning with the origin of chemistry as found in alchemy, it traces the history of the science down to the present time. The author gives a clear account of the genesis of chemical theory, and at the same time presents a comprehensive history of the progress of knowledge of the various departments. The account of the development of the atomic theory is particularly well done."

NEW AND THOROUGHLY REVISED EDITION.

8vo, Cloth, 18s.

A COMPLETE TREATISE on INORGANIC AND ORGANIC CHEMISTRY. By Sir HENRY E. ROSCOE, F.R.S., and Prof. C. SCHORLEMMER, F.R.S.

Vol. III.—THE CHEMISTRY OF THE HYDROCARBONS, and their Derivatives, or ORGANIC CHEMISTRY. Six Parts. Part III. New and Thoroughly Revised Edition.

CHEMICAL NEWS:—"As a systematic treatise on chemistry the work in its entirety has no equal in the English language."

ACADEMY:—"The authors are evidently bent on making their book the finest treatise on systematic chemistry in the language."

IRON:—"One of the best treatises in our language."

Globe 8vo, 6s.

MIXED METALS OR METALLIC ALLOYS. By ARTHUR H. HIORNS, Principal of the School of Metallurgy, Birmingham and Midland Institute.

CHEMICAL NEWS:—"The best manual of alloys to be met with in the English language."

BY THE SAME AUTHOR.

PRACTICAL METALLURGY AND ASSAYING. A Text-book for the use of Teachers, Students, and Assayers. With Illustrations, Globe 8vo, 6s.

A TEXT-BOOK OF ELEMENTARY METALLURGY. For the use of Students. Globe 8vo, 4s.

IRON AND STEEL MANUFACTURE. A Text-book for Beginners. Illustrated. Globe 8vo, 3s. 6d.

THE NEW PATENT WATKIN ANEROID BAROMETER.

PRICES FROM £5 to £7. ALSO MADE WITH SIZE.

Amongst many unsolicited Testimonials the following has been received by the maker:—

EDINBURGH, May 31, 1889.

DEAR SIR,—I have just returned from a six weeks' stay at the Ben Nevis Observatory, and while there had an opportunity of testing the admirable qualities of your new "Watkin" Aneroid. The result has been most satisfactory, the extreme error noted being only about $\frac{1}{100}$ of an inch. During my stay at the Observatory the Aneroid was frequently tested by taking it down 2000 feet and then comparing it with the standard on my return. The results obtained speak volumes for the high-class workmanship and great accuracy you have attained in the manufacture of this instrument.

(Signed) R. C. MOSSMAN, F.R.M.S., Observer, Scott. Met. Soc.

To be obtained of all Opticians and Wholesale Houses.

SESSION commences OCTOBER 1. Full Prospectus and List of Scholarships on application to the REGISTRAR, University College, Liverpool.

UNIVERSITY COLLEGE, LONDON.

The Session of the Faculty of Medicine will commence on OCTOBER 1. Introductory Lecture at 4 p.m., by Prof. VICTOR HORSLEY, M.B., B.S., F.R.S., Assistant Surgeon to University College Hospital.

The Examinations for the Entrance Exhibitions will commence on SEPTEMBER 23.

Scholarships, Exhibitions, and Prizes of the value of £800 are awarded annually.

In University College Hospital about 3000 In-patients and 35,000 Out-patients are treated during the year. Thirty-six appointments, eighteen being resident, as House Surgeon, House Physician, Obstetric Assistant, &c., are filled up by competition during the year, and these, as well as all Clerkships and Dresserships, are open to Students of the Hospital without extra fee.

Prospectuses, with full information as to Classes, Prizes, &c., may be obtained from the College, Gower Street, W.C.

E. A. SCHÄFER, F.R.S., Dean.
J. M. HORSBURGH, M.A., Secretary.

LECTURER on APPLIED MECHANICS.

The Technical Education Committee of the County Council of the County of Southampton wish to engage the Services of a LECTURER on APPLIED MECHANICS (who would also conduct Classes in Mechanical Drawing), subject to the sanction of the Appointment by the County Council. The Engagement would be in the first instance for Six Months only, dating from October 1, at a Fee of £150, and Railway Fares.

Applications, with copies of not more than Six Testimonials, should reach the undersigned not later than AUGUST 8.

VAUGHAN CORNISH, B.Sc., F.C.S.
13 Southgate Street, Winchester.

LIVING SPECIMENS FOR THE MICROSCOPE.

Algæ, Infusoria, Rotifera, Entomostraca, Polyzoa, and other examples of "Pond-life" are supplied at 1s. per Tube, Post free, with Drawing and Description. Volvox globator, Stentor cæruleus, Brachionus rubens, Plumatella repens, and Paludicella Ehrenbergi now good. Amœba, Protococcus, Vorticella, Hydra, Crayfish, &c., for Students of Biology.

List Post Free.

THOMAS E. BOLTON,
FARLEY ROAD, MALVERN LINK.

CITY AND GUILDS OF LONDON INSTITUTE.

PRESIDENT: H.R.H. THE PRINCE OF WALES, K.G.

CHAIRMAN OF COUNCIL: THE RIGHT HON. THE EARL OF SELBORNE, F.R.S.

SESSION 1891-92.

The Matriculation or Entrance Examination for the CENTRAL INSTITUTION will be held on SEPTEMBER 21-24 and for the Day Department of the TECHNICAL COLLEGE, FINSBURY, on SEPTEMBER 29.

CENTRAL INSTITUTION.

The Courses of Technical Instruction at the Central Institution of the City and Guilds of London Institute are adapted to the requirements of persons who are preparing to become Civil, Mechanical, or Electrical Engineers, Chemical and other Manufacturers and Teachers.

MATHEMATICAL DEPARTMENT, under the direction of Prof. HENRICI, F.R.S. ENGINEERING DEPARTMENT, under Prof. UNWIN, F.R.S., M.I.C.E. (Dean of the Institution). PHYSICAL AND ELECTRICAL DEPARTMENT, under Prof. AYRTON, F.R.S. CHEMICAL DEPARTMENT, under Prof. ARMSTRONG, Ph.D., F.R.S.

The NEW SESSION COMMENCES on SEPTEMBER 30. The Entrance Examination will be held on SEPTEMBER 21-24.

Programme and full Particulars of Courses of Instruction, and of the Entrance Scholarships, on application at the Central Institution, Exhibition Road, or at the Office of the City and Guilds Institute, Gresham College, E.C.

TECHNICAL COLLEGE, FINSBURY.

The DAY CLASSES at the City and Guilds Technical College, Finsbury, provide Technical Instruction for Mechanical and Electrical Engineers and Technical Chemists, and are under the direction of Prof. S. P. THOMPSON, D.Sc., F.R.S., Principal of the College, Prof. J. PERRY, F.R.S., and Prof. R. MELDOLA, F.R.S.

The NEXT SESSION commences on OCTOBER 6. The Entrance Examination will be held on SEPTEMBER 29.

For further Particulars of Day and Evening Classes, Scholarships, &c., apply at the College, Leonard Street, City Road, E.C., or at the Office of the City and Guilds Institute.

JOHN WATNEY Hon. Secretary.

City and Guilds of London Institute, Gresham College, E.C.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL,

ALBERT EMBANKMENT, LONDON, S.E.

The WINTER SESSION of 1891-92 will open on THURSDAY, OCTOBER 1, when the Prizes will be distributed at 3 p.m. by Sir G. M. HUMPHRY, M.D., LL.D., F.R.S.

TWO ENTRANCE SCIENCE SCHOLARSHIPS of 125 guineas and £60 respectively, open to all first-year Students, will be offered for competition. The Examination will be held on September 26, 28, and 29, and the subjects will be Chemistry and Physics, with either Physiology, Botany, or Zoology, at the option of Candidates.

Scholarships and Money Prizes of considerable value are awarded at the Sessional Examinations, as also several Medals.

Special Classes are held throughout the year for the Preliminary Scientific and Intermediate M.B. Examinations of the University of London.

All Hospital Appointments are open to Students without charge.

The Fees may be paid in one sum or by instalments. Entries may be made separately to Lectures or to Hospital Practice, and special arrangements are made for Students entering in their second or subsequent years; also for Dental Students and for Qualified Practitioners.

A Register of approved Lodgings is kept by the Medical Secretary, who also has a List of local Medical Practitioners, Clergymen, and others who receive Students into their houses.

Prospectuses and all particulars may be obtained from the Medical Secretary, Mr. GEORGE RENDLE.

G. H. MAKINS, Dean.

Sale by Auction.

FRIDAY, JULY 31.

MICROSCOPIC APPARATUS, &C.

MR. J. C. STEVENS will sell by Auction at his Great Rooms, 38 King Street, Covent Garden, on FRIDAY, JULY 31, at half-past 12 precisely, several valuable Binocular and Monocular Microscopes by ROSS, SMITH, and BECK, &c. Also, Immersion and other Objectives, and a great variety of Microscopic Apparatus and Fittings. Also, Photographic, Chemical, and Electrical Apparatus, and Miscellaneous Property.

On view Day prior, 2 to 5, and Morning of Sale, and Catalogues had.

UNIVERSITY COLLEGE OF NORTH WALES (BANGOR).

SESSION 1891–92 will open on SEPTEMBER 29.

DEPARTMENTS of PHYSICS, CHEMISTRY, and BIOLOGY.

PHYSICS ..... { Professor, A. GRAY, M.A. / Demonstrator, D. M. LEWIS, M.A.

CHEMISTRY ... { Professor, J. J. DOBBIE, M.A., D.Sc. / Demonstrator, G. MACGOWAN, Ph.D. (Leipzig).

BIOLOGY ..... Professor, R. W. PHILLIPS, M.A., B.Sc.

The Classes and Laboratory Courses of this College are arranged to suit the requirements of Students of Practical Science, as well as of Students preparing for University and other Examinations. Two Years of the Three Years' Course required for Graduation in Science at the University of Edinburgh may be taken at this College, and the Lectures in Chemistry, Botany, and Zoology are recognized by the Universities of Edinburgh and Glasgow as qualifying for the Medical Degrees of those Universities. One *Annus Medicus* may be taken at this College.

The extensive Laboratories (Physical, Chemical, and Biological) are fully equipped for Study and Research.

In the Physical Department a Steam-Engine and Dynamo-Electric Machinery, &c., have been provided for the Teaching of Electrical Engineering. A Special Course has been arranged in this subject.

Laboratory Fees (per Term)

on the scale of £1 1s. for six hours a week, in each Department.

A considerable number of Scholarships and Exhibitions are open for Competition at the beginning of each Session, and several are awarded at the close of each Session on the result of the Year's work.

For full information as to Science and Arts Courses, apply for Prospectus to the REGISTRAR,

W. CADWALADR DAVIES.

Bangor, July 1, 1891.

UNIVERSITY COLLEGE, BRISTOL.

CHEMICAL DEPARTMENT.

PROFESSOR—SYDNEY YOUNG, D.Sc.
LECTURER—ARTHUR RICHARDSON, Ph.D.

The SESSION 1891–92 begins on OCTOBER 8. Lectures on Inorganic, Organic, Advanced, Analytical, and Photographic Chemistry will be delivered during the Session. The Laboratories are fitted with the most Recent Improvements for the study of Practical Chemistry in all its branches. In the Evening, Lectures on Inorganic Chemistry, at Reduced Fees, are delivered. Several SCHOLARSHIPS are tenable at the College.

CALENDAR, containing full information, price 1s. (by post, 1s. 3d.).

For Prospectus and further particulars, apply to

JAMES RAFTER, Secretary.

HARTLEY INSTITUTION, SOUTHAMPTON.

TECHNICAL TEACHERS.

The Hartley Council require the services of—

(1) A GEOMETRICAL and ENGINEERING TEACHER. Salary, £150 per annum and Government grants.

(2) An ASSISTANT ART MASTER, specially qualified to teach Modelling in Clay and Wood-carving. Salary, £100 per annum and certain Government grants.

Full particulars of these Appointments will be sent on Application.

Applications for these Appointments must be received by the SECRETARY on or before THURSDAY, AUGUST 6.

THE YORKSHIRE COLLEGE; LEEDS.

Applications are invited for the Appointment of LECTURER on GEOLOGY for one year from October 1, at a Stipend of £100, for which 10 Lectures on the Geology of Coal Mining and 30 Lectures on Geology as connected with the Agricultural Course will be required. Opportunity will be given for Extension Lecturing in Yorkshire, for which a payment of £2 per Lecture will be made. The Lecturer would be required to reside in or near Leeds during the six winter months. The Appointment will probably be renewable.

Applications will be received by the SECRETARY of the College up to SEPTEMBER 19.

THE AGRICULTURAL COLLEGE, ASPATRIA.

PRINCIPAL—DR. H. J. WEBB, B.Sc.

Thorough practical and scientific Training in Agriculture. Preparation for the Colonies. Students gained the First, Third, and Fourth Scholarships of the Royal Agricultural Society, 1888; First in Agriculture Junior Scholarships, 1889; First in Agriculture Senior Scholarships, 1890.

PUPIL ASSISTANT.—Youth of Scientific Tastes and Training Wanted.—Prof. GEDDES, University Hall, Edinburgh.

F. H. BUTLER, M.A. Oxon., Assoc.R.S.Mines,

NATURAL HISTORY AGENCY,

158 BROMPTON ROAD, LONDON,

Dealer in Rocks, Minerals, Fossils, and other Objects of Scientific Interest.

The Specimens recently added to Stock include examples of the rare Cæsium mineral Pollucite, from Maine, also of Beryllonite and Hiddenite, U.S.A.; fine sections of Siphonia in Flint; Fossils and Sedimentary and Igneous Rocks from the Llandovery, Caradoc, Llandeilo, Wenlock, and Upper Lingula Beds near Builth, Church Stretton, and Aymestry; Trilobites and Acrocystella from the Shineton Shales; Foraminifera and other Fossils from the Thanet Sands, near Ramsgate; a selection of Ornamental Shells and Malayan Butterflies; and Micro-sections of "Flaser-Gabbro" from Scotland and Germany, of Diamantiferous "Blue Ground" from Kimberley, and of Chert with Organisms. A varied assortment of Microscopical Glass Slips and Covers always on hand.

JAMES R. GREGORY,

Mineralogist and Geologist.

SPECIAL AND TYPICAL COLLECTIONS FOR STUDENTS, LECTURERS, MUSEUMS, &c. EVERY REQUISITE FOR PRACTICAL WORK. ROCK SPECIMENS, AND ROCK SECTIONS FOR MICROSCOPIC EXAMINATION. THE LARGEST STOCK AND GREATEST VARIETY IN LONDON. NEW LISTS NOW READY.

New Catalogue of Mineral Specimens,

Arranged for the Selection of Single Specimens, &c., with Prices. Also New Lists of Rare Minerals, Rock Specimens, Geological Apparatus, Collections, Hammers, and Microscopic Sections of Rocks.

And may be had post free on application at the Repository and Museum,

88 CHARLOTTE STREET, FITZROY SQUARE, LONDON.

MINERALOGY.

SAMUEL HENSON,

97 REGENT STREET, LONDON, W.

ESTABLISHED 1840. *Late 277 STRAND.*

Choice Mineral Specimens, Gem Stones, Carved Opals, Polished Agates Rock Crystal Balls, Fossils, Rocks, and Rock Sections.

LATEST ARRIVALS.

Beautiful Coloured Crystal of Ruby, Burmah, very fine Emeralds on the Matrix, Pink Garnets, Hyalite, San Luis Potosi, finely crystallized Azurite, rare form of Rhodocroisite, fine New Zealand Jade Meri-Meri.

MICRO-PETROLOGY.

Rock Sections for the Microscope, of special value and interest:—Porphyritic Basalt, Lion's Haunch, Edinburgh; Dolerite with Porphyritic Augite, Crawford John, Lanarkshire; Perlitic Pitchstone, Saxony; Pikrite, Inchcolm, Firth of Forth; Thulite, Norway; Siliceous Oolite, Pennsylvania; a Siliceous Rock with a perfect oolitic structure.

1s. 6d. each; extra large Sections, 1s. 9d. and 2s.

Collections of Minerals and Rocks for Prospectors and Students.

CATALOGUES POST FREE.

THOMAS D. RUSSELL,

78 NEWGATE STREET, LONDON, E.C.

CONCHOLOGY.

New and Interesting Shells from New Guinea, Borneo, Philippine Islands, &c.

COLLECTIONS PURCHASED.

All kinds of Glass-Topped Boxes, &c., at Moderate Prices.

THE TEACHING OF FORESTRY.[1]

A Manual of Forestry. By William Schlich, C.I.E., Ph.D. Vol. II. (London: Bradbury, Agnew, and Co., 1889.)

IN a loop of the Main river in Lower Franconia, east of Aschaffenburg, rises an extensive mountainous country, clothed with almost unbroken forest of singular beauty and of enormous value. It is the Spessart, in old times known as the home and haunt of great highway robbers, but also known from time immemorial as the home of the best oak timber in Germany. The red sandstone of the Trias, which everywhere is the underlying rock in this extensive forest country, makes a light sandy loam, which, where deep, is capable of producing tall, cylindrical, well-shaped stems. Having grown up, while young, in a densely crowded wood, the oak here has cleared itself of side branches at an early age. Hence these clean straight stems, which in the case of spruce, silver fir, and other forest trees, may justly be said to be the rule, but which the oak does not produce, save under these and similarly favourable circumstances. The species here is *Quercus sessiliflora*: this species does not form pure forests, but is always found mixed with other trees, the hornbeam, the beech, and on the lower slopes of the western Schwarzwald, the silver fir. In the Spessart, the beech is associated with the oak, in the same manner as the bamboo is the chief associate of the teak tree in Burma.

In publishing his manual of forestry, the author wished in the first instance to place in the hands of the students at the Coopers Hill Forest School a handbook to facilitate their studies. That Forest School was, it may be remembered, established in 1885, in connection with the Royal Indian Engineering College at the same place, in order to give the needful professional training to young Englishmen who desired to enter the Indian Forest Department. Accordingly, when the first volume of that manual appeared in 1889, it was natural that some, who took a strong interest in the progress of forest management in the British Indian Empire, were surprised that the book did not deal with Indian trees, and that its teaching related to the oak, the beech, the Scotch pine, and other trees of Europe. By some of these zealous friends of Indian forestry the book was pronounced a failure, because it did not treat of Indian forest trees.

The principles which guide the forester in the proper treatment of his woods are the same all over the world, in India as well as in Europe. But while the application of these principles to the treatment of Indian forests is not more than thirty-five years old, the methodical and systematic treatment of European forests is of old standing, and has stood the test of experience. In the teak forests of Burma, the bamboo has a position similar to that of the beech in the oak forests of the Spessart. Oak and teak are both trees with comparatively light foliage. Pure woods of these species, while young, are sufficiently dense to shade the ground, whereas at an advanced age the wood gets thin, the canopy light, and the result is that grass and weeds appear, and that by the action of sun and wind the soil hardens and is less fertile than the loose porous soil, which is shaded by dense masses of foliage. Hence the advantage of associates, which, like the beech in Europe and the bamboo in Burma, shade the ground with their dense foliage and enrich it by the abundant fall of their leaves. But it is not only the condition of the ground which is improved by these useful associates. Teak and oak have this specialty also in common, that, when growing up alone, their stems, instead of running up into clean cylindrical boles, are apt to throw out side branches, which greatly impair the market value of the log. But when growing up in dense masses with their natural associates, these latter, crowding in as they do on all sides, around the oak in the Spessart and the teak in Burma, prevent the development of side branches and thus produce clean and regularly shaped stems.

In these and many other ways are the associates of the teak and of the oak useful friends, so to speak. Under certain circumstances, however, and at certain periods of their life, they are dangerous enemies to their more valuable companions. On the sandstone of the Spessart and elsewhere, the beech, as a rule, has a more vigorous growth than the oak; it gets the upper hand, and, unless it is cut back or thinned out in time, the oak, if both are growing up in an even mixture, has no chance. The bamboo is even more formidable as an enemy of the young teak tree. Though the teak may have had a long start; if a crop of bamboos—either the shoots of old rhizomes, or perhaps the result of general seeding of the old bamboo forest, cleared away to make room for the teak—springs up among it, the teak is doomed. As soon as the rhizomes of the bamboo have acquired sufficient strength, they produce, within a few weeks, during the rains, such a profusion of full-sized shoots, say 20 to 30 feet high, that the young teak trees among them are throttled and extinguished.

The similarity in the relations of teak and bamboo in Burma, and of oak and beech in the Spessart, has led foresters in both countries to devise similar arrangements for the regeneration of these forests. In the Spessart, when the old timber in a compartment of the forest is cut, the best places for the growth of the oak are selected, and the oak, which here sells at the rate of from 2*s.* to 3*s.* a cubic foot for sound and well-shaped pieces, is sown on soil most suitable for its development; while the beech, the timber of which only fetches about one-fifth of that amount, is allowed to reproduce naturally from self-sown seedlings over the rest of the area. Among the oak also a certain but small proportion of beech springs up, and even where pure oak woods may be the result of these proceedings, it will not be difficult, when they are sufficiently advanced, to introduce such a proportion of beech as will secure their satisfactory development. In the same way in Burma, selected areas are cleared for the growth of teak in the original forest, the clearance being effected and the teak planted with the aid of that rude mode of shifting cultivation, known as the Toungya system.

Many other instances might be quoted, in which similar practices have developed in the rearing and tending of woods in Europe and in India. The principles of sylviculture are the same everywhere, and the application of these principles to the treatment of woods in different

[1] See NATURE, vol. xli. p. 121.

Digitized by Google

parts of the globe has, in many instances, led to the adoption of similar methods; hence Dr. Schlich was right in selecting the timber trees of Europe to illustrate the application of these principles in the manual before us.

Sylviculture, the author explains, is the formation and tending of woods, and he divides his subject into four chapters. The first of these chapters treats of preliminary works, such as choice of species, fencing and reclamation of the soil by draining, the fixation of shifting sands, the breaking through of an impermeable substratum (pan) and the like. In regard to the fixation of shifting sands, an interesting account is given on p. 33 of the methods which have been most successfully practised on the west coast of France, in order to stop the progress inland of the coast dunes, and to clothe these ridges of rolling sand with a productive forest of the cluster pine (*Pinus Pinaster*). A belt, in many places five miles wide, along the coast of Gascony, and considerably further north, has in this manner been reclaimed, and the steady progress of the sand, which had covered large areas of fields and meadows, and which had destroyed numerous villages, has thus been arrested.

Chapter ii. deals with the formation of woods by artificial and natural means. The Spessart, which has been mentioned above, is an instance in which both artificial and natural means are used in order to effect the regeneration of the forest, so as to insure the production of timber of the highest possible commercial value. In most large forest districts on the continent of Europe, both the natural and artificial method are employed. As the author says on p. 178, neither the one nor the other system "is the best at all times and under any circumstances; only a consideration of the local conditions can lead to a sound decision as to which is preferable in a given case." In France, for instance, a country highly favoured by a climate uniformly moist and mild, where most forest trees produce seed more frequently than in Germany, natural reproduction may, broadly speaking, be said to be the rule and planting the exception. But in France, also, planting operations on a large scale have been carried out on the dunes of the west coast as well as on bare mountain-sides of the Alps, the Cevennes, and the Pyrenees, and, wherever necessary, planting is resorted to, to supplement the natural regeneration of the forests.

An instance in which over a large extent of country the forests are regenerated artificially may be found in the State forests of the kingdom of Saxony, together with most of the communal and many of the private forests in that country. The State forests of Saxony cover an area of 432,000 acres, and by far the larger portion of this area is stocked with pure spruce forest treated on a short rotation of eighty years, and regenerated artificially by planting. The high prices realized in this industrious and thickly populated country, even for timber of small sizes, have gradually led to the adoption of this system; and the State forests of the kingdom of Saxony are a pattern of methodical and most successful management. The forest ranges, all in charge of highly trained superior forest officers, are small, containing not more than 2000 to 3000 acres each, and many of these ranges have a steady regular annual yield of 140 cubic feet of timber per acre, and furnish a net revenue, after deducting all charges, general and local, of 100 marks per hectare, which corresponds to forty shillings an acre.

But in Great Britain also, and in Scotland especially, is the system of rearing forests by planting well understood, and it is practised over large areas economically and successfully. French as well as German foresters of great practical experience have repeatedly expressed their high sense of the skill and ability with which large plantations are formed in Great Britain at a comparatively moderate cost. But even foresters and wood-managers in Great Britain may learn a good deal from this portion of Dr. Schlich's book. Their attention might specially be directed to the author's remarks on p. 113, regarding transplants which have developed a lopsided root system, "because the trenches, into which the pricked out seedlings are placed, are often made so shallow, that the root system of the plants, instead of assuming a natural position in the ground, is altogether bent to one side."

That section of the second chapter which deals with the natural regeneration of woods, necessarily divides itself into two portions: first, natural regeneration by seed; and second, by shoots and suckers (pollards and coppice). Concise brevity is one of the great merits of Dr. Schlich's manual, and it doubtless was necessary to curtail, and to make a rigid selection of the most important matters. But the treatment of coppice woods and of coppice under standards might perhaps have been a little less brief.

As regards natural regeneration by seed, the Black Forest in South-Western Germany may be quoted as an instance where, over extensive areas, the forest is chiefly regenerated by natural means. The splendid logs of spruce and silver fir, which are floated down the Rhine in numberless huge rafts, have all grown from self-sown seedlings, and most of the young timber now growing up has had the same origin. The timber which is brought to market from these forests is much older and heavier than that sold in the forests of Saxony, but the results of management are to some extent similar. There are some forest ranges in the Schwarzwald, both in the grand-duchy of Baden and in the kingdom of Württemberg, which yield the same annual quantity of timber per acre, and furnish the same rate of net revenue to their proprietors, as those of Saxony. The term of rotation, of course, is much longer, and the system of natural reproduction takes time, hence the money value of the growing stock of old timber is very large, much larger per acre than in Saxony. The interest, therefore, on the capital invested (value of land plus growing crop) is less in this case. The discussion of these matters, however, does not appertain to sylviculture, but to forest management, with which the author will deal in a subsequent volume of his work.

As already mentioned, in France the natural regeneration of forests is the rule, chiefly owing to its wonderfully favourable climate. Large areas, mainly of private and communal forest, are managed in admirable style, as coppice woods and as coppice under standards. The treatment of high timber forests also, and their regeneration from self-sown seedlings, by means of a regular system of successive cuttings, has in France been brought to a high state of perfection. This circumstance renders the French forests specially valuable as a field of instruction for foresters proceeding to India. For in that large country, though planting has been commenced and must

Digitized by Google

necessarily be carried on in some instances on a large scale, yet every effort ought to be made to develop good systems of natural regeneration in the different provinces.

On pp. 132-64 the author gives a clear account of the different systems which have in course of time been devised, in order to effect the natural regeneration of woods by seed. Under the more favourable climate of France the desired object is generally effected by a simple and to some extent uniform system of successive cuttings. In Germany, on the other hand, where droughts are frequent, frosts severe, and where good seed years generally are of rare occurrence, the system of regular successive cuttings, which originated in Germany, in many cases was found to fail, and accordingly, some sixty or seventy years ago, the tide set in in favour of artificial reproduction. A reaction, however, has for good reasons taken place in many parts of the country, and during the last thirty years German foresters have been busy in adapting the system of natural regeneration to the peculiar conditions of each forest district. Indian forest students should go to France, in order to become impressed with the fact that under favourable circumstances natural regeneration of high forests may be effected by a simple and easy system of treatment. In German forests, on the other hand, they should learn how the difficulties of a climate frequently unfavourable have been successfully overcome by devising systems of treatment suitable to the requirements of each locality, and the knowledge here acquired will be most useful, nay, necessary, to them in India, where the conditions of climate by no means always favour the natural regeneration of the more valuable forest trees.

Space forbids a full discussion of this most important and interesting subject. This portion of Dr. Schlich's book, if supplemented by the study of forests on a large scale, particularly in Germany, will be most useful to foresters who may be called upon to devise methods of forest treatment in other parts of the globe, be it India, Australia, South Africa, or North America.

Closely allied to the subject just adverted to is what the author says in the fourth section of the same chapter regarding the formation of mixed woods. Pure woods, consisting of one species only, are exposed to various risks, from which mixed woods are exempt. Hence, in most Continental forests, there has of late years been a strong tendency in the direction of favouring the growth of mixed woods, such as oak and beech, oak and hornbeam, oak and silver fir, Scotch pine and beech, and the like. It goes without saying, that operations in this direction, in order to be successful, must be guided by careful study of the mode of growth and of the peculiar requirements of the different species in different places and under different conditions. Something has been said above regarding the treatment of mixed woods of oak and beech in the Spessart. But it does not follow that oak and beech behave in the same manner everywhere. On certain kinds of shale, belonging to the Devonian formation, for instance, the oak rather than the beech has the tendency to take the lead, and here mixed woods of oak and beech can be produced from self-sown seedlings much more easily than would be possible on the sandstone of the Spessart. Again, along the foot of the Western Schwarzwald, where, as already stated, the silver fir is associated with the oak, this tree, though a shade-bearer like the beech, renders it much easier for the oak to hold its own in an even-aged mixed wood, because in its early youth it grows very slowly, thus giving the oak a good start in life.

Chapter iii. teaches how woods should be tended during early youth and afterwards. Passing over what the author says regarding cleaning of young woods and pruning, we come to thinning operations. On p. 209 an interesting statement is given showing the number of trees per acre in certain mixed woods of the Schwarzwald. The figures are as follows:—

Age of wood in years.	Number of trees per acre.
20	3960
40	1013
60	449
80	346
100	262

Thus, during the life of a wood, and this holds good in all cases, the number of trees per acre decreases gradually from several thousand to a comparatively small number at maturity. When, as usual, the object is to produce high class timber, with clean well-shapen stems, the rule is, as the author correctly states it: "The wood should be thinned lightly until towards the end of the principal height growth; then the thinnings should gradually become heavier, so as to assist a selected number of trees by the gradual removal of all those which are inferior and diseased." In its youth the wood is crowded, the young trees maintaining a severe struggle for existence. The weaker trees are suppressed and some are actually killed, while the rest are either dominant trees, with their head well above the others, or dominated, though not suppressed. Formerly thinnings were generally done by rule of thumb, the dead, oppressed, and a portion of the dominated trees being removed. But it is obvious that, when the object is to produce valuable timber, thinnings must so be managed, that the trees which are destined to attain the term of rotation, and which will form the final crop to be cut down, in the example here given, 262 trees per acre 100 years old, shall be sound and regularly shaped. It is obvious that to attain this object dominant trees also may occasionally have to be removed, if unsound, spreading, or irregular shaped, and this is properly recognized by the author. He justly adds that in such cases dominated and even suppressed trees may have to be spared in order to keep the ground well under cover. Such would be the practice in the case of woods consisting of one species only, or of several species of equal value. Where one species, such as oak or teak, is of much greater value than the others, all thinnings must, as a matter of course, be so arranged as to favour this species at the expense of the rest.

So far concerning the thinning of crowded woods. The last section of the same chapter deals with the tending of open woods for the production of large timber. Into this subject, which is one of some difficulty, though of great importance, it would lead too far to enter on the present occasion.

Chapter iv. contains sylvicultural notes on British forest trees, with notes (by Prof. H. Marshall Ward) on botanical characters serving to distinguish the principal British forest trees. The two species of oak dealt with in

Digitized by Google

the sylvicultural notes are *Quercus pedunculata* and *Quercus sessiliflora*. Botanists are well aware that the maintenance of distinctive characters between these two and others of the European species of *Quercus* is difficult; so much so, that the best authorities on English trees have decided to re-establish the old species of Linnæus, *Quercus Robur*, and to regard the two species named merely as forms or varieties. The forester has a different task, and for him the mode of growth and the requirements of these two oaks are so different that he must keep them separate. It will suffice to mention one point, which has not perhaps been brought out sufficiently by the author. The mixed woods in which *Quercus sessiliflora* is associated with the beech, the hornbeam, and the silver fir have been mentioned above. In natural high forests this species is only found in company with other trees, and particularly with the three kinds named. The pure or nearly pure coppice woods of *Quercus sessiliflora* in France and Western Germany are an exception; these, however, have been converted into pure woods by the long-continued cutting out of beech, hornbeam, and soft woods. *Quercus pedunculata*, on the other hand, *does* form pure high timber forests of considerable extent. Such are found both in Northern and Southern Europe, not on hilly ground, but always on deep alluvial soil. Instances are the forests on low ground along the Elbe and other rivers of North Germany, the magnificent pure forests of that tree on the banks of the Adour river near Dax in Gascony, and similar ones in the peninsula of Istria, south of Trieste. There is underwood on the ground in the forests named, but it merely consists of thorns and low shrubs. The two species, *Quercus sessiliflora* and *pedunculata* have different requirements and require somewhat different treatment. This, however, is a small matter. These sylvicultural notes are most valuable, and it is satisfactory that the Weymouth pine and the Douglas fir have been included among them.

The second volume of Dr. Schlich's manual, like the first, will be an immense help to the students who are trained at the Coopers Hill College for forest service in India. It will be a great boon to all who are charged with the management of forests in India, in the colonies, and in the United States of North America. And it may perhaps be hoped that in Great Britain also this excellent book will in course of time tend to awaken a more general interest in the good management of its woodlands, which are very extensive, and which some day may be of considerable importance and of great value to their proprietors.

D. BRANDIS.

THE APPLICATIONS OF MODERN CHEMISTRY.

Dictionary of Applied Chemistry. Vol. II. (Eau-Nux). (London: Longmans, 1891.)

THE editor of a dictionary of applied science, such as the volume before me, has in these days no enviable task to perform: much is required of him, and the difficulties with which he has to contend are great. Prof. Thorpe has acquitted himself well, for though there may be, indeed there are, many points with which the expert can find fault, yet these are generally matters of detail, and on the whole the work has been satisfactorily done, so that the second volume will be found to be quite up to the high level of the first. The industries which owe their foundation to the science of chemistry now progress with such giant strides, that processes which last year were the newest and best may this year be so improved as to be rendered obsolete, so that an article printed at the commencement of a volume may become antiquated before the last article is in type, whilst data unattainable when the article was written are superseded by some more recently published. As an example of this, I may take that upon "gas coal," written by a most competent authority, Mr. Lewis Wright. On p. 177 will be found a table giving the weight of coal carbonized by all the authorized gas undertakings in the kingdom, exclusive of those of local authorities, for the year ending March 25, 1886. Since these tables were printed, a Board of Trade return for 1890 has been published. In 1886, 8,378,904 tons of coal were carbonized; in 1890 the figure rose to 9,663,011. In 1886 the mileage of mains was 18,967; in 1890 it had increased to 21,584. These numbers point out the enormous extent of the coal-gas industry in this country, and show clearly that it is not suffering from the competition of electric lighting; indeed, this competition is favourable to the sale of gas, for we see that our streets are now better lighted than formerly, and the consumption of gas in many shops is increased, in order to vie with the splendour of their neighbours' electric light.

As a critic is bound to criticize, I may point out some few faults of commission and omission which have struck me in reading through this generally excellent article.

The important steps which have recently been taken in many large works for charging and drawing the gas retorts by mechanical means are barely referred to. Great economy is doubtless effected where such labour-saving mechanical appliances have been adopted, and a description of these would have been of interest, as the labour agitation in our gas-works has brought engineers face to face with this question. Another point upon which a statement would have been of value is the most improved arrangements of the purifying house, and the methods adopted for charging and discharging the purifiers. That "the whole of the sulphuretted hydrogen, carbonic acid, and carbon disulphide can be easily and economically removed" (p. 200) by a combined system of oxide and lime, and with a proper arrangement of purifiers, is a statement to which many gas engineers will demur. The London companies, especially, who have a legal standard limit for sulphur compounds, find it both difficult and expensive to keep down the impurities to the necessary point. The illustrations given in this article are scarcely worthy of the letter-press. Figs. 22 and 23 do not give an idea of the construction of a modern gas-holder, some of which now have the enormous capacity of ten million cubic feet, and are marvels of engineering skill. A description of the latest improvements would have added interest to the article.

Digitized by Google

As an instance of the rapid progress of an industry interfering with an adequate account being published in the early pages of such a volume, I may refer to the article on electro-plating, by Prof. W. C. Williams, which, although giving a clear account of the older processes, scarcely represents the position of to-day. Thus no reference is found to recent methods of the electro-deposition of metals, as, for example, the Elmore copper process, or to that of plating by aluminium; nor does any mention occur of the electric power suitable or used for depositing metals.

To justify the opinion that this volume is no unworthy successor to that published last year, I would refer to a few articles which are certainly the best I know on their several subjects. First, "Explosives," by W. H. Deering, coming from the pen of one who has had long experience in the Chemical Department of the Royal Arsenal, Woolwich, is, as we should expect, up to the level of the time, and in every respect excellent. Second comes Prof. Percy Frankland's article on fermentation. No one is more competent than he to write on this most fascinating subject, and his article reads like a novel, and even better, for "truth is stranger than fiction"; and Percy Frankland tells his story so clearly and well that I will not spoil the pleasure of his readers—and they ought to be many—by any attempt to abstract its results. Thirdly, the article on "Matches," by Mr. Clayton, may be cited as an admirable treatise on this important branch of chemical manufacture, condensed into 24 pages. Not the least important contribution are the nine tables giving, in chronological order, lists of the numerous patented and other inventions in this department of chemical technology. Lastly, I will select Mr. Wynne's exhaustive article on naphthalene as perhaps the most able and valuable in the whole volume. When we learn that, although it occupies 65 pages of the dictionary, it treats exclusively of the derivatives of one hydrocarbon, and only of those of them which are now used in the arts, and valuable for industrial purposes, we begin to form an idea of the extent and importance of the results of modern organic research, which has opened out regions illimitable, leading to practical results such as the chemists of the last generation would have deemed impossible.

In a dictionary of applied science the question of selection is even more difficult than in a similar work of pure science. Here the knowledge and tact of the editor are especially called into play. Prof. Thorpe has, I think, chosen well, but here and there some pages are taken up with matters of which I should be glad to learn the present industrial value—for in the future all may have a use. Thus I find close together the following: elaidic acid, ericolin, erucic acid, erythrol—all, doubtless, compounds of scientific interest, but hardly, I would venture to suggest, of industrial importance.

As I said of the first volume, so I may say of the second—that it does credit to the authors of the articles, to the editor, and to the public-spirited publishers. It is good that English scientific literature keeps up its prestige for thoroughness, clearness, and conciseness, and that in this volume of the dictionary no falling off from this standard is visible. H. E. ROSCOE.

THE FISHES OF SWITZERLAND.

Faune des Vertébrés de la Suisse. Par Victor Fatio. Vol. V. "Histoire naturelle des Poissons." 2me partie, avec 4 planches, pp. 576. Supplémens, pp. 13. (Genève et Bale: H. Georg, 1890.)

AS more than eight years have elapsed since the publication of the last volume of the "Faune des Vertébrés de la Suisse," I may preface this notice with a few words as to the general scope and progress of this important work. The first volume, published in the year 1869, was devoted to a detailed account of the Mammals of Switzerland; the third (1872) to the Reptiles and Batrachians; and the fourth (1882) to a part of the Fishes (Acanthopterygians and Cyprinoids); the second volume, which will contain the Birds, being still in course of preparation.

The part now published, which is the fifth of the series, treats of the remaining half of the fishes, notably the Salmonoids, which take up nearly two-thirds of the volume, and whose study has probably occupied the author by far the better half of the eight years which he has devoted to its preparation.

As regards the plan of the work, the thoroughness and originality with which the author treats his subject, and the fairness of his criticism of his predecessors, I may be allowed to refer to what I have said in my notice of the first volume of the Swiss ichthyology (NATURE, vol. xxvii. p. 220); stating again that "this work rises far above the level of a local publication, and is of as great value to the student of European freshwater fishes as to the Swiss naturalist."

The species treated of in the present volume are the following: 3 loaches, 2 shad, 8 Coregoni, 1 grayling, 1 salmon, 1 trout, 1 char, 1 pike, 1 Silurus, 1 eel, 1 burbot, 1 sturgeon, 3 lampreys. These bring the total number of Swiss freshwater fishes to 51.

The hydrographic system of Switzerland comprises the head-waters of four rivers, viz. the Rhine, Rhone, Po, and Danube. The first contributes the largest contingent to the Swiss fish fauna, viz. 42 species; however, this number is reduced to 28 in the upper course of the river, above the falls of Schaffhausen. At an altitude of between 600 and 900 m. the majority of the Cyprinoids, and between 1000 and 1100 m. the perch, salmon, eel, and burbot disappear. Only five species remain at that altitude, viz. the miller's thumb, minnow, loach (*N. barbatulus*), grayling, and trout—species which likewise have the greatest horizontal range in a northward direction. Between 1800 and 1900 m., first the grayling and the loach are lost, and then successively the trout, miller's thumb, and minnow. The trout, however, can still subsist in lakes up to 2630 m., into which this fish has been introduced. The Rhine contributes five types of fishes to the Swiss fauna which are not found in the other hydrographic systems, viz. *Acerina* (the pope), *Rhodeus*, the salmon, the sea lamprey, and the stickleback. The absence in the southern and eastern waters of the four first is readily accounted for by their distribution generally; but it seems very singular that a fish like the stickleback, which in the west of Europe extends far southwards, and reaches even Algeria, and which is

Digitized by Google

supposed to be capable of easy transportation by aquatic birds, should not have made its way into the other river-systems.

The fishes contributed by the Rhone fall into two categories—one comprising those of the part of the River Doubs which is within the political boundaries of Switzerland; the other including the species of the Rhone proper above the "Perte." The latter are computed to be 20 in number, and do not call for special remarks.

The fishes of the Po show a marked difference from those of the Rhine and Rhone. This system is represented in Switzerland by the tributary Ticino, into which 23 species enter, out of a total number of 44 Po species. Although there is no mechanical obstacle to their ascent, the fishes of the Po, used to a warmer climate, avoid ascending into the cold waters from the Alps; and M. Fatio observes, also, that generally these southern fish do not ascend to the same high altitudes as those of the Rhine. Eight of the Ticino species are strangers to the rest of Switzerland, viz. a goby (*Gobius*), which has ascended from the sea; five Cyprinoids, which may be regarded as southern representatives of northern forms; *Cobitis tænia* and *Alosa finta*.

Of the 68 species belonging to the fauna of the Danube, only four find their way into Switzerland through the River Inn, viz. the miller's thumb, minnow, grayling, and trout. This is owing to the great elevation of this river at its entrance into the country (1000 metres).

Ichthyologists will turn with particular interest to that part of the volume which contains Dr. Fatio's views on, and his treatment of, the Salmonids; for my own part, I could not help feeling some surprise at what appears to me a somewhat inconsistent mode of dealing with this subject. Whilst the author distinguishes not less than eight Swiss forms worthy of binominal designation in the genus *Coregonus*, he admits, besides one species of char (*Salmo umbla*), two equivalent forms only in the genus *Salmo*, viz. the salmon and the trout, for which latter the collective term *Salmo lacustris* is chosen. If a student of the European fauna, or any part of it, arrives at the conclusion that the various forms of river, lake, and sea trout cannot, and should not, be held to be deserving of specific distinction, no one will deny that there are very strong arguments in favour of this view. In my own experience it does not seem to be desirable to adopt that course—first, because there are certain well characterized and well localized forms which the practical fisherman will always distinguish, and of which the naturalist has, somehow, to take notice; and, secondly, because the ichthyologist who goes beyond the narrow limits of a fauna, and has to deal with the trout of the whole northern hemisphere, is compelled by technical considerations to admit those distinctions. I myself go a step further, and consider it a mistake not to separate, specifically, from the extremely variable *Salmo fario*, such strongly differentiated forms as *Salmo lemanus*, *S. marsitii*, *S. venernensis*, or the Loch Leven trout of the older authors. But if, as is Dr. Fatio's opinion, no taxonomic value is to be assigned to the characters by which those forms of trout are differentiated, then I cannot see why in *Coregonus*, a closely related genus of the same geological age and distribution, similar organic modifications should be considered to have a different bearing.

As is well known, there are some very obscure facts in the life-history of Salmonoids which greatly contribute to the difficulties of their study. Dr. Fatio discusses them very fully, but we must pass over the deductions he draws from them, with the exception of the phenomenon of sterility as a cause of change in the outward appearance of a fish. Sterility among Salmonoids is apparently much more common in Switzerland than in British waters; but ever since Siebold has drawn attention to it, its effects seem to me to have been exaggerated. At any rate, I have received specimens as, and, indeed, with all the outward characters of, the so-called sterile trout of Lake Constance, which had fully matured ova.

Like errata, appendices of works are only too often overlooked; I would therefore mention that the present volume concludes with important supplements to those which contain the Mammalia and Reptilia.

The volume is illustrated with four plates—one representing the *Bondelle* of the Lake of Neufchâtel, the others various details of structure, chiefly of Salmonoids.

I trust that before many years Dr. Fatio will be able to complete his work, for which, not only his countrymen, but every student of the European fauna, owe him a debt of gratitude.

ALBERT GÜNTHER.

THE HISTORY OF MARRIAGE.

The History of Human Marriage. By Edward Westermarck. (London: Macmillan and Co., 1891.)

BY "history" our author means "natural history" (p. 19), and his reason for using the odd term "human marriage" is that "marriage, in the natural history sense of the term, does not belong exclusively to our species" (p. 6). According to him, "marriage is nothing else than a more or less durable connection between male and female, lasting beyond the mere act of propagation till after the birth of the offspring." In this sense marriage is "an almost universal institution among birds," and "occurs as a rule among the monkeys, especially the anthropomorphous apes, as well as in the races of men" (p. 20). Among mankind it is universal, and in all probability is "an inheritance from some ape-like progenitor" (p. 538). In this book, therefore, marriage is taken to mean what ordinary people call "pairing," and the professed subject of the volume is the natural history of the habit of pairing in the human race. But surely, on any proper use of terms, marriage is not simple pairing, but such pairing as is protected and regulated by law, or by the public opinion which in rude societies stands for law. And the history of an institution which is controlled by public opinion and regulated by law is not natural history. The true history of marriage begins where the natural history of pairing ends.

Mr. Westermarck's definition leads him to go at length into various topics that really belong to natural history, but have little or nothing to do with the history of marriage in the ordinary sense of the word; such as sexual selection, and the means used by one sex to attract the other. But he also deals with polyandry, kinship through females only, infanticide, exogamy—all of which belong to the sphere of law and custom, within which his definition of marriage is totally inapplicable. To treat these topics as essentially a part of the natural history of

Digitized by Google

pairing involves a tacit assumption that the laws of society are at bottom mere formulated instincts; and this assumption really underlies all our author's theories. His fundamental position compels him, if he will be consistent with himself, to hold that every institution connected with marriage that has universal validity, or forms an integral part of the main line of development, is rooted in instinct, and that institutions which are not based on instinct are necessarily exceptional, and unimportant for scientific history. One does not expect a tacit assumption to be carried out with perfect consistency; but, on the whole, Mr. Westermarck's results correspond with his assumption, and have no evidence to satisfy anyone that is not prepared to share the assumption with him.

To show this at length would exceed the limits of a short review; let us, however, take, as a crucial test, Mr. Westermarck's explanation of the origin of exogamy. He believes that exogamy and all laws of incest originate in an instinctive aversion to sexual intercourse between persons living closely together from early youth (p. 320), and the origin of this instinct he explains as follows. He thinks it can be proved that consanguineous marriages are detrimental to the species. Now,

"among the ancestors of man, as among other animals, there was, no doubt, a time when blood-relationship was no bar to sexual intercourse. But variations, here as elsewhere, would naturally present themselves; and those of our ancestors who avoided in-and-in breeding would survive, while the others would gradually decay and ultimately perish. Thus an instinct would be developed which would be powerful enough, as a rule, to prevent injurious unions. Of course, it would display itself simply as an aversion on the part of individuals to union with others with whom they lived; but these, as a matter of fact, would be blood relations, so that the result would be survival of the fittest" (p. 352).

The obvious and fatal objection to this theory is that it postulates the existence of groups which through many generations (for the survival of the fittest implies this) avoided wiving within the group. And this is, in fact, a well-established custom of exogamy, so that the theory begins by postulating the very custom that it professes to explain. Moreover, it is questionable whether Mr. Westermarck's theory even helps to explain the wide diffusion of exogamy. For where wiving outside the local group is the rule, all neighbouring groups mingle their bloods, and consanguineous marriages are not escaped.

It is not surprising that Mr. Westermarck, with his habit of looking at the whole subject from a biological point of view, should have little sympathy with the speculations of a man like McLennan, to whom marriage is not a mere fact of natural history, but a relationship resting on contract and approved by custom or law; and who in all his investigations gives weight to the action of human intelligence as the decisive factor in social progress. But it is a pity that this lack of sympathy has sometimes prevented our author from appreciating the full scope of McLennan's methods and arguments. What is said about the Levirate at pp. 510–14 could not have been written if Mr. Westermarck had carefully read the discussion of the subject in "The Patriarchal Theory"; nor, to mention a trivial matter, would he in that case have made the error of confounding the Hindu Levirate with the Nyoga (p. 514, *note*). And here I may also note that the criticism of McLennan's views of exogamy does not take account of the posthumous and very important paper published in the *English Historical Review* for January 1888.

These are details: what is more to be regretted is that Mr. Westermarck has not learned, as he might have done from McLennan, a sounder method of handling the evidence drawn from the usages of rude societies. The very possibility of reconstructing the history of human progress rests on the fact that all over the world mankind has been moving in the same general direction, but at very various rates, and that careful reasoning, aided especially by the observation of cases which exhibit a state of transition (*e.g.* from one type of kinship to another), enables us to bring out the order in which the various observed types of social structure succeed one another. Of all this, Mr. Westermarck does not seem to have the least idea. He collects facts about the prevalence of kinship through males or through females, about forbidden degrees, and so forth, without ever rising to the conception that the evidence is good for anything more than an *inductio per enumerationem simplicem*. This is not the way in which real progress can be made.

W. ROBERTSON SMITH.

OUR BOOK SHELF.

Geological Map of Monte Somma and Vesuvius. Constructed by H. J. Johnston-Lavis, M.D., M.R.C.S., B.-ès-Sc., F.G.S., &c., during the Years 1880–88. Scale, 1 : 10,000 (6·33 inches = 1 mile). In Six Sheets, with a Pamphlet entitled "A Short and Concise Account of the Eruptive Phenomena and Geology of Monte Somma and Vesuvius." (London: George Philip and Son, 1891.)

DURING the latter half of last century, the changes taking place in Vesuvius were carefully studied and faithfully chronicled by an English diplomatist—Sir William Hamilton; in the closing years of the present century, the famous volcano has found an equally indefatigable investigator and historian in the person of an English medical man resident in Naples—Dr. Johnston-Lavis. In 1884, Dr. Johnston-Lavis laid before the Geological Society an elaborate memoir, in which he detailed the theoretical conclusions at which he had arrived after long and patient study of the various sections exposed on the flanks of Somma and Vesuvius. He has now published a very valuable addition to this work, in the form of a map constructed on the basis of the topographical surveys of the Italian Government, and coloured in accordance with the views to which he has been led by his long and painstaking geological labours.

In his general memoir on the geology of Somma and Vesuvius, the author has divided the time covered by the history of the volcano into four "eras," and these again into eight "phases," while some of the latter are subdivided into "periods." In colouring the map, it has, of course, not been found possible to give expression to anything like such a minute classification of the rocks composing the mountain as is implied in such a scheme. The legend on the map recognizes as the great landmarks in the past history of the volcano the paroxysm of 79 A.D. and the great eruption of 1631. The pamphlet accompanying the map, however, gives a very useful and readable abstract of the earlier memoir; and the map and descriptive pamphlet together cannot fail to prove of the greatest service to all students of vulcanology. By their

Digitized by Google

publication, Dr. Johnston-Lavis has added one more to the long list of valuable services which he has rendered to geological science.

Les Sciences Naturelles et l'Éducation. Par T. H. Huxley. Édition Française. (Paris: Baillière et Fils, 1891.)

THIS is a translation of various essays with which all English students of Prof. Huxley's writings have long been familiar. Most of them deal with various aspects of the question as to the true place of science in a proper system of education; and no one who has read them in their original form is likely to have forgotten the philosophical power with which the subject is discussed, or the admirable lucidity, strength, and grace of the writer's style. With his educational papers Prof. Huxley has associated his well-known essays on Descartes and Auguste Comte, which cannot fail to be of interest to French readers. He contributes to the volume a short preface, in which he refers with satisfaction to the astonishing advance that has been made in the recognition of science as an instrument of education. He warns men of the younger generation, however, that the battle has only been half won, and that much serious work will have to be done to secure the triumph of the principles for which he has contended Of the translation it may be enough to say that Prof. Huxley cordially commends it as a faithful rendering of his thought.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

W. E. Weber.

IN the article on Wilhelm Weber (NATURE, July 9, p. 229) no mention is made of the fact that Weber and Gauss in 1833 invented and constructed a telegraph connecting the Physical Laboratory of the University in Göttingen with the Observatory. In Germany they are for this reason said to be the inventors of telegraphy. This is, to say the least, a somewhat sweeping statement, as the possibility of communicating by electricity was known long before that time. However, there is no doubt that Weber and Gauss played some part in introducing telegraphy into practice. For my part I consider the purely scientific work of either of the two men more glorious. For the enormous practical consequences of telegraphy have nothing to do with the scientific merit of the invention. Nevertheless I think that an article on Wilhelm Weber would not be complete without entering into this subject. C. RUNGE.

Hanover, Technische Hochschule, July 13.

[Conducting wires were erected between the Göttingen Observatory and the Physical Cabinet of the University, distant about three-quarters of an English mile, in order to obtain accurate comparisons of the clocks. But, in addition to systematic daily transmission of time, the wires were from the first frequently used for telegraphic purposes, though, with the first arrangements, only two letters could be sent in a minute.—G. C. F.]

Earthquake Shocks in Italy and Australia.

BY a telegram from London, which appeared in the newspapers here on the 12th and 13th inst., information is given of a severe earthquake in Italy (about Vesuvius) on June 7 (Sunday). On that day, several distinct and well-marked shocks were felt over parts of the south of Australia, and as there may be some connection between these seismic disturbances in both hemispheres, I give below the times and other information of the disturbances experienced here.

None of the disturbances reported in Australia seem to have been more than a "shake" or *sharp tremor* sufficient to shake windows and rattle crockery, &c., but they were enough, in some instances, to produce feelings of nausea.

June 7, at 2.5 p.m., the first disturbance occurred, and was felt all around Melbourne and over a surrounding area of 360 square miles.

June 7, at 2.45, another shake (not so great as the first) was also felt; in this case it was felt most severely to the east of Melbourne.

June 7, at 7.20, smart shock felt at Kapunda, South Australia.

June 7, at 6.45, slight shock felt at Stockport, South Australia The direction of motion is variously given as from north-west to south-east, south-east to north-west, and south-west to north-east, north to south, south to north, &c. The conclusion arrived at is that the wave was from south to north nearly. The approximate geographical positions of the several localities where these disturbances occurred are as follows:—

	Lat.	Long.
	° ′	° ′
Stockport	34 21 S. ..	138 57 E.
Kapunda	34 21 S. ...	138 46 E.
Melbourne ...	37 50 S. ...	144 58 E.

Melbourne, June 15. R. L. J. ELLERY.

P.S.—It is quite probable the shocks felt at Kapunda and Stockport were one and the same, as time is not very strictly kept in districts distant from large towns in Australia.

Force and Determinism.

I SEE nothing to criticize in Mr. Dixon's middle paragraph, wherein he accurately summarizes some of the definitions of mechanics, except that I should prefer to express the meaning of his last sentence by saying that, if in any department something simulated the functions of, say, energy, without obeying its precise mechanical laws, then the distinction between energy and that something should be clearly recognized, and another name be given to it.

I find it rather common for "life" to be thought of and classed under the head energy, either by the use of a phrase such as "vital energy," or in a more direct way; the reason being apparently that organisms while living simulate some of the functions of energy, and cease to do so when dead. It was against this confusion that I wrote on p. 491 (vol. xliii.).

Life has not yet been included in the domain of physics, neither has it, so far as I am aware, been much studied under the head biology.

And yet the disturbing action of live animals will have to be formulated and attended to some day, even in physics; for, though they generate no energy nor affect its amount in the slightest degree, they certainly control it and direct it in channels it would not otherwise have taken. The question is, How do they manage this? And one answer that may be given is, By exerting directive or guiding forces on matter.

Of course they are not limited to this, but in so far as they do work their action is fairly understood: the energy displayed by a gang of navvies is known to be derived from the little tin cans they bring with them: the energy is not theirs but their victuals', they simply direct it. But how comes it that they can direct the energy of victuals and atmosphere into the erection of the precise bridge or other structure which has been planned? What determines the direction of the transfer of energy?

The same question may doubtless be asked in connection with inanimate activity: I would not be understood as assuming for certain any clear or essential difference between the two cases; but in neither case do I know the answer.

The action of force in doing work, *i.e.* transferring and transforming quantities of energy, has been thoroughly attended to.

The action of force in directing and guiding the transfer of matter and energy does not seem to me to have been seriously contemplated.

In his most recent book ("The Philosophical Basis of Evolution") Dr. Croll attacks the problem, and says that guidance is effected by "determinism" not by force. But that cannot be admitted; for without force the motion of matter cannot be changed in direction any more than in speed. *Force* is certainly necessary to direct the motion of matter, it is *energy* only which is unnecessary; for any transfer of energy that may occur is an accidental, not an essential, concomitant.

I determine to move an object: it may be only my finger, or it may be a wheelbarrow. In so far as I do any work in the action I do so at the expense of my food, and there is nothing but a chemical difficulty about that. The mystery begins when one

Digitized by Google

asks how I manage to direct that energy along a definite path so as to produce a willed result. The only answer I know is, "By a nervous impulse liberated from brain centres." But what is it that is thus liberated? and what pulls the trigger to liberate it?

By mechanical analogy one would say that energy can only be guided by force, and that force must therefore be exerted in the brain cells; but, if so, the relation between force, which is a mechanical thing, and will or life, or whatever it is, which is a psychological thing, demands investigation.

I trust that Mr. Lloyd Morgan will help me to get my ideas on these subjects straighter, and will point out if I have made any assertions which are obviously erroneous or grotesque. The borderland of psychology and physics is the last place in which I would like to dogmatize; and in a letter like this I see no harm in airing confessedly immature and groping notions, in the hope that ventilation may clear the air. So far as physics only is concerned, I have stated how I regard the phrase "expenditure of energy" in the *Philosophical Magazine* for June 1885

With regard to the crux raised in Mr. Dixon's last paragraph, that nothing but matter can exert force, because the acting matter must receive an equal opposite momentum, it may perhaps be just worth noticing that an infinite mass can absorb any amount of momentum without receiving a trace of energy or being itself in any way affected. OLIVER J. LODGE.

Liquid Prisms.

I OBSERVE in NATURE of July 2 (p. 207), that it is stated Herr Wolter has recently recommended α-monobromnaphthalene as a substance peculiarly fitted for study of the ultra-violet part of the spectrum, by reason of its high dispersive power and transparency for the ultra-violet rays.

Perhaps I may be permitted to state that Mr. Madan published an account of its dispersion and refractive power in the *Phil. Mag.*, and recommended its use in liquid prisms. Having made use of many other substances, including methyl salicylate, I gave this a trial. For ordinary work it would be excellent if colourless; but unfortunately, no matter how free from colour it may be when freshly prepared, long-continued use causes it to become yellow, and in considerable thicknesses even dark brown. For the ultra-violet rays it is undoubtedly better than carbon disulphide, but nevertheless practically useless, as the line N, which it is said to transmit, has a wave-length of 3580, so that only about one-half of the ultra-violet solar rays are observable with it. In metallic spectra almost all lines of interest lie between 3580 and 2000. A liquid which I considered to possess much superior optical properties is *mercuric methide;* it is perfectly colourless, and of such density that flint glass will float upon it. When the glass is immersed it becomes invisible, consequently the refraction and dispersion of the liquid are probably exceptionally high. As far as I can recollect, being without access to my notes, a thickness of 50 millimetres freely transmitted all rays to about λ 2900—that is to say, the entire solar spectrum. Unfortunately, it has its drawbacks, in being somewhat volatile, and its vapour highly poisonous.

The Identification of Templeton's British Earthworms.

BETWEEN the years 1829 and 1836 the first series of Loudon's *Magazine of Natural History* appeared in nine volumes. In the last volume we find some notes on earthworms by Templeton, which have proved somewhat puzzling to students of more recent times. I have been fortunate enough to follow Templeton in some of his researches, and am able to correct and verify certain of his statements.

The *Lumbricus xanthurus*, Temp. (*op. cit.*, ix. 235), is the angler's gilt tail, and as such is synonymous with *Lumbricus puter*, Hoffm., and *Dendrobæna Boeckii*, Eisen. *Lumbricus gordianus*, Temp. (*loc. cit.*), is undoubtedly the mucous worm (*Allolobophora mucosa*, Eisen), or one of its near allies, all of which are to be found of a pale rosy colour coiled up into a knot at certain times of the year.

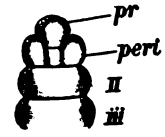
It is to *Lumbricus omilurus* (= *Omilurus rubescens*, Temp., *loc. cit.*), however, that I wish to direct special attention. Grube, in 1851 ("Familien der Anneliden," p. 101), placed it, with Templeton's other worms, in a list of species which were insufficiently characterized for systematic purposes. Vejdovsky, in 1884 ("System und Morph. der Oligochæten," p. 62), places it among the questionable species without note or comment, and, so far as I can gather, no one has been able to throw light upon it since.

Templeton says the worm is never larger than half the size of *L. terrestris*, L., is of a bright reddish-brown, with the tail very flat, and the body *unfurnished with a belt at the position of the sexual organs*. It would be very easy to suppose from this somewhat vague account that the writer had only seen immature specimens; but a little careful study of his words shows that he knew what he was writing, and that his worms were mature. Now a mature species of *Lumbricus* without a clitellum is certainly an anomaly, and needs investigation.

While collecting Annelids recently, I came across half-a-dozen specimens which at first sight exactly resembled *Lumbricus rubellus*, Hoffm. I took them home for verification, and immediately observed the difference. I had obtained with them typical specimens of *rubellus*, which enabled me to make a careful comparison of the two species in a living state.

The following is a description of the worm as I wrote it down before observing Templeton's account.

Colour dark brown, iridescent on the dorsal surface anteriorly, becoming lighter towards the posterior extremity, which is flesh-coloured or light red, pink ventrally. Prostomium dovetailing completely into the peristomium, and posses-ing a transverse groove in the middle, as shown in the accompanying sketch.



Lumbricus rubescens. Segments 1 to 3 with prostomium entirely cutting the first segment or peristomium.

Segments not annulated (or divided by transverse rings). Length about 3 inches, total number of segments about 120. Setæ in couples as in typical Lumbricus. Male or spermiducal pores on segment 15 with papillæ, which, however, do not extend over the neighbouring segments. Body cylindrical in front, flattened posteriorly. The dorsal pore between 5 and 6. It appeared at first between 7 and 8, but by using polarized light on the cuticle when spread on a glass slip the whole series of pores in one or two specimens became clearly visible from the fifth segment backwards.

On the ventral surface prominent papillæ appeared on segments 28 and 29, such as are often seen on typical *L. agricola*, Hoffm. Now came the crucial question, Is there no clitellum? By studying all the examples carefully, I found that they agreed in one particular. The segments 34 to 39 differed in structure from the rest on the dorsal surface. On the under surface from 33 to 40 were differentiated, and showed a glandular structure, while the band representing the tubercula pubertatis extended distinctly along the ventral surface of 35, 36, 37, 38.

This description of the external characters shows the worm to be a decided Lumbricus, tested by Dr. Benham's definition in "An Attempt to Classify Earthworms"; but it differs from every one of our British species, especially in the backward position and inconspicuous nature of the clitellum. I am unable to refer it definitely to any of the European species, and propose that for the present it should be known as *Lumbricus rubescens* (Temp.), thus retaining the two names from Templeton's synonyms which are most appropriate to what I regard as the species intended by him.

I may add that I have recently found one or two other earthworms in Yorkshire which have not yet been recorded as British, and will form interesting additions to our Annelid fauna.

Idle, near Bradford, July 15. HILDERIC FRIEND.

Copepoda as an Article of Food.

DURING recent years a good deal has been said amongst marine zoologists of the use, as a food supply, that might be made of the enormous numbers of Copepoda that swarm in the surface-waters of the sea, and the Prince of Monaco has pointed out the value this widely-distributed nutritious matter might have to shipwrecked sailors; but I am not aware that anyone has yet actually made the experiment of cooking and eating Copepoda, so the following record may be of some interest.

Digitized by Google

While townetting during the last few days about the North Cape, we have had some large hauls of Copepoda; and it occurred to us last night, while watching the midnight sun off the entrance to the Lyngen Fjord, that one gathering might be spared from the preserving bottle and devoted to the saucepan. We put out one of the smaller townets (3½ feet long, mouth 1 foot in diameter) from 11.40 p.m. to midnight, the ship going dead slow, and traversing in all, say, a mile and a half during the 20 minutes. The net when hauled in contained about three tablespoonfuls of a large red Copepod (*Calanus finmarchicus*, I think), apparently a pure gathering—what Haeckel would call a monotonic plankton. We conveyed our material at once to the galley, washed it in a fine colander, boiled it for a few minutes with butter, salt, and pepper, poured it into a dish, covered it with a thin layer of melted butter, set it in ice to cool and stiffen, had it this morning for breakfast on thin bread-and-butter, and found it most excellent. The taste is less pronounced than that of shrimps, and has more the flavour of lobster. Our 20 minutes' haul of the small net through a mile or two of sea made, when cooked in butter, a dishful which was shared by eight people, and would probably have formed, with biscuit or bread, a nourishing meal for one person. It would apparently, in these seas, be easy to gather very large quantities, which might be preserved in tins or dishes, like potted shrimps. W. A. HERDMAN.

S.Y. *Argo*, Tromsö, Norway, July 13.

Are Seedlings of *Hemerocallis fulva* specially Variable?

I SHALL be grateful to any of your readers who will write and let me know their experiences as to the variability of seedlings of *Hemerocallis fulva*, or who will raise it from seed in fair quantity, and kindly communicate to me their results, which shall be duly acknowledged.

My reason is this: there is in the formation of the pollen in this plant a peculiarity which, according to Weismann's views, should lead to exceptional variability in the seedlings; but, so far as I know, we have no evidence on the subject.

MARCUS M. HARTOG.

Royal University, Dublin, July 9.

The Green Sandpiper.

ON Sunday last, July 12, I saw flying round a large pool in Essex, a specimen of the *green sandpiper*. It flew leisurely round the pool, and seemed as if it were not far from its summer home. I think, therefore, that the bird must be nesting in the county, and probably in the neighbourhood.

Can any of your correspondents inform me whether the nest has been found anywhere, in recent years, in England?

ARGYLL.

Argyll Lodge, Kensington, July 17.

LIQUIDS AND GASES.[1]

ALMOST exactly twenty years ago, on June 2, 1871, Dr. Andrews, of Belfast, delivered a lecture to the members of the Royal Institution in this hall, on "The Continuity of the Gaseous and the Liquid States of Matter." He showed in that lecture an experiment which I had best describe in his own words:—

"Take, for example, a given volume of carbonic acid at 50° C., or at a higher temperature, and expose it to increasing pressure till 150 atmospheres have been reached. In the process, its volume will steadily diminish as the pressure augments; and no sudden diminution of volume, without the application of external pressure, will occur at any stage of it. When the full pressure has been applied, let the temperature be allowed to fall, until the carbonic acid has reached the ordinary temperature of the atmosphere. During the whole of this operation, no break of continuity has occurred. It begins with a gas, and by a series of gradual changes, presenting nowhere any abrupt alteration of volume, or sudden evolution of heat, it ends with a liquid.

[1] Lecture delivered by Prof. W. Ramsay, F.R.S., at the Royal Institution, on Friday, May 8.

"For convenience, the process has been divided into two stages—the compression of the carbonic acid, and its subsequent cooling. But these operations might have been performed simultaneously, if care were taken so to arrange the application of the pressure and the rate of cooling, that the pressure should not be less than 76 atmospheres when the carbonic acid had cooled to 31°."

I am able, through the kindness of Dr. Letts, Dr. Andrews' successor at Belfast, to show you this experiment, with the identical piece of apparatus used on the occasion of the lecture twenty years ago.

I must ask you to spend some time to-night in considering this remarkable behaviour; and, in order to obtain a correct idea of what occurs, it is well to begin with a study of gases, not, as in the case you have just seen, exposed to high pressures, but under pressures not differing greatly from that of the atmosphere, and at temperatures which can be exactly regulated and measured. To many here to-night, such a study is unnecessary, owing to its familiarity; but I will ask such of my audience to excuse me, in order that I may tell my story from the beginning.

Generally speaking, a gas, when compressed, decreases in volume to an amount equal to that by which its pressure is raised, provided its temperature be kept constant. This was discovered by Robert Boyle in 1660; in 1661 he presented to the Royal Society a Latin translation of his book, "Touching the Spring of the Air and its Effects." His words are:—

"'Tis evident, that as common air, when reduced to half its natural extent, obtained a spring about twice as forcible as it had before; so the air, being thus compressed, being further crowded into half this narrow room, obtained a spring as strong again as that it last had, and consequently four times as strong as that of common air."

To illustrate this, and to show how such relations may be expressed by a curve, I will ask your attention to this model. We have a piston, fitting a long horizontal glass tube. It confines air under the pressure of the atmosphere—that is, some 15 pounds on each square inch of area of the piston. The pressure is supposed to be registered by the height of the liquid in the vertical tube. On increasing the volume of the air, so as to double it, the pressure is decreased to half its original amount. On decreasing the volume to half its original amount, the pressure is doubled. On again halving, the pressure is again doubled. Thus you see a curve may be traced, in which the relation of volume to pressure is exhibited. Such a curve, it may be remarked incidentally, is termed an hyperbola.

We can repeat Boyle's experiment by pouring mercury into the open limb of this tube containing a measured amount of air; on causing the level of the mercury in the open limb to stand 30 inches (that is, the height of the barometer) higher in the open limb than the closed limb, the pressure of the atmosphere is doubled, and the volume is halved. And on trebling the pressure of the atmosphere the volume is reduced to one-third of its original amount; and, on adding other 30 inches of mercury, the volume of the air is now one-quarter of that which it originally occupied.

It must be remembered that here the temperature is kept constant; that it is the temperature of the surrounding atmosphere.

Let us next examine the behaviour of a gas when its temperature is altered, when it becomes hotter. This tube contains a gas—air—confined at atmospheric pressure by mercury, in a tube surrounded by a jacket or mantle of glass, and the vapour of boiling water can be blown into the space between the mantle and the tube containing the air, so as to heat the tube to 100°, the temperature of the steam. The temperature of the room is 17° C., and the gas occupies 290 divisions of the scale. On blowing in steam, the gas expands, and on again equalizing pressure, it

Digitized by Google

stands at 373 divisions of the scale. The gas has thus expanded from 290 to 373 divisions, *i.e.* its volume has increased by 83 divisions; and the temperature has risen from 17° to 100°, *i.e.* through 83°. This law of the expansion of gases was discovered almost simultaneously by Dalton and Gay-Lussac in 1801; it usually goes by the name of Gay-Lussac's law. Now, if we do not allow the volume of the gas to increase, we shall find that the pressure will increase, in the same proportion that the volume would have increased had the gas been allowed to expand, the pressure having been kept constant. To decrease the volume of the gas, then, according to Boyle's law, will require a higher initial pressure; and if we were to represent the results by a curve, we should get an hyperbola, as before, but one lying higher as regards pressures. And so we should get a set of hyperbolas for higher and higher temperatures.

We have experimented up to the present with air—a mixture of two gases, oxygen and nitrogen; and the boiling-points of both of these elements lie at very low temperatures: − 184° and − 193°·1 respectively. The ordinary atmospheric temperature lies a long way above the boiling-points of liquid oxygen and liquid nitrogen at the ordinary atmospheric pressure. But it is open to us to study a gas, which, at the ordinary atmospheric temperature and pressure, exists in the liquid state; and for this purpose I shall choose water-gas. In order that it may be a gas at ordinary atmospheric pressure, however, we must heat it to a temperature above 100° C., its boiling-point. This tube contains water-gas at a temperature of 105° C.; it is under ordinary pressure, for the mercury columns are at the same level in both the tubes and in this reservoir, which communicates with the lower end of the tube by means of the india-rubber tubing. The temperature 105° is maintained by the vapour of chlorobenzene, boiling in the bulb sealed to the jacket, at a pressure lower than that of the atmosphere.

Let us now examine the effect of increasing pressure. On raising the reservoir, the volume of the gas is diminished, as usual; and nearly in the ratio given by Boyle's law; that is, the volume decreases in the same proportion as the pressure increases. But a change is soon observed; the pressure soon ceases to rise; the distance between the mercury in the reservoir and that in the tube remains constant, and the gas is now condensing to liquid. The pressure continues constant during this change; and it is only when all the water-gas has condensed to liquid water that the pressure again rises. After all gas is condensed, an enormous increase of pressure is necessary to cause any measurable decrease in volume, for liquid water scarcely yields to pressure, and in such a tube as this, no measurements could be attempted with success.

Representing this diagrammatically, the right-hand part of the curve represents the compression of the gas; and the curve is, as before, nearly a hyperbola. Then comes a break, and great decrease in volume occurs without rise of pressure, represented by a horizontal line; the substance in the tube here consists of water-gas in presence of water; the vertical, or nearly vertical line represents the sudden and great rise of pressure, where liquid water is being slightly compressed. The pressure registered by the horizontal line is termed the "vapour-pressure" of water. If, now, the temperature were raised to 110°, we should have a greater initial volume for the water-gas; it is compressible by rise of the mercury as before, the relation of pressure to volume being, as before, represented on the diagram as an approximate hyperbola; and as before, condensation occurs when volume is sufficiently reduced, but this time at a higher pressure. We have again a horizontal portion, representing the pressure of water-gas at 110° in contact with liquid water; again, a sharp angle where all gaseous water is condensed, and again a very steep curve, almost a straight line, representing the slight decrease of volume of water produced by a great increase of pressure. And we should have similar lines for 120°, 130°, 140°, 150°, and for all temperatures within certain limits. Such lines are called isothermal lines, or shortly "isothermals," or lines of equal temperature, and represent the relations of pressure to volume for different temperatures.

Dr. Andrews made similar measurements of the relations between the pressures and volumes of carbon dioxide, at pressures much higher than those I have shown you for water. But I prefer to speak to you about similar results obtained by Prof. Sydney Young and myself with ether, because Dr. Andrews was unable to work with carbon dioxide free from air, and that influenced his results. For example, you see that the meeting-points of his hyperbolic curves with the straight lines of vapour-pressures are curves, and not angles; that is caused by the presence of about 1 part of air in 500 parts of carbon dioxide; also the condensation of gas was not perfect, for he obtained curves at the points of change from a mixture of liquid and gas to liquid. We, however, were more easily able to fill a tube with ether free from air, and you will notice that the points I have referred to are angles, not curves.

Let me first direct your attention to the shapes of the curves in the diagram. As the temperature rises, the vapour-pressure lines lie at higher and higher pressures, and the lines themselves become shorter and shorter. And finally, at the temperature 31° for carbon dioxide, and at 195° for ether, there ceases to be a horizontal portion at all; or rather, the curve touches the horizontal at one point in its course. That point corresponds to a definite temperature, 195° for ether; to a definite pressure, 27 metres of mercury, or 35·6 atmospheres; and to a definite volume, 4·06 cubic centimetres per gram of ether. At that point the ether is not liquid, and it is not gas; it is a homogeneous substance. At that temperature ether has the appearance of a blue mist; the striæ mentioned by Dr. Andrews, and by other observers, are the result of unequal heating, one portion of the substance being liquid, and another gas. You see the appearance of this state on the screen.

When a gas is compressed, it is heated. Work is done on the gas, and its temperature rises. If I compress the air in this syringe forcibly, its temperature rises so high that I can set a piece of tinder on fire, and by its help explode a little gunpowder. If the ether at its critical point be compressed by screwing in the screw, it is somewhat warmed, and the blue cloud disappears. Conversely, if it is expanded a little by unscrewing the screw, and increasing its volume, it is cooled, and a dense mist is seen, accompanied by a shower of ether rain. This is seen as a black fog on the screen.

I wish also to direct your attention to what happens if the volume given to the ether is greater than the critical volume—on increasing the volume, you see that it boils away and evaporates completely; and also what happens if the volume be somewhat less than the critical volume—it then expands as liquid, and completely fills the tube. It is only at the critical volume and temperature that the ether exists in the state of blue cloud, and has its critical pressure. If the volume be too great, the pressure is below the critical pressure; if too small, the pressure is higher than the critical pressure.

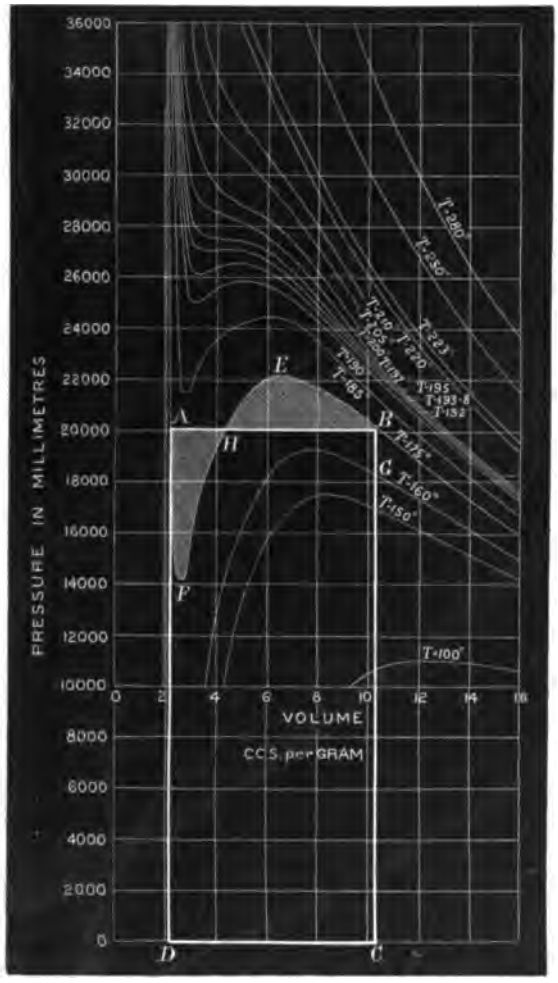
Still one more point before we dismiss this experiment. At a temperature some degrees below the critical temperature, the meniscus, *i.e.* the surface of the liquid, is curved. It has a skin on its surface; its molecules, as Lord Rayleigh has recently explained in this room, attract one another, and it exhibits surface-tension. Raise the temperature, and the meniscus grows flatter; raise it further, and it is nearly flat, and almost invisible; at the critical temperature it disappears, having first become quite flat. Surface-tension, therefore, disappears at the critical point.

Digitized by Google

A liquid would no longer rise in a narrow capillary tube; it would stand at the same level outside and inside.

It was suggested by Prof. James Thomson, and by Prof. Clausius about the same time, that if the ideal state of things were to exist, the passage from the liquid to the gaseous state should be a continuous one, not merely at and above the critical point, but below that temperature. And it was suggested that the curves, shown in the figure, instead of breaking into the straight line of vapour-pressure, should continue sinuously. Let us see what this conception would involve.

On decreasing the volume of a gas, it should not liquefy at the point marked B on the diagram, but should



still decrease in volume on increase of pressure. This decrease should continue until the point E is reached. The anomalous state of matters should then occur, that a decrease in volume should be accompanied by a decrease of pressure. In order to lessen volume, the gas must be exposed to a continually diminishing pressure. But such a condition of matter is of its nature unstable, and has never been realized. After volume has been decreased to a certain point, F, decrease of volume is again attended by increase of pressure, and the last part of the curve is continuous with the realizable curve representing the compression of the liquid, above D.

Dr. Sydney Young and I succeeded, by a method which I shall briefly describe, in mapping the actual position of the unrealizable portions of the curve. They have the form pictured in this figure. The rise from the gaseous state is a gradual one; but the fall from the liquid state is abrupt.

Consider the volume 14 cubic centimetres per gram on the figure. The equi-volume vertical line cuts the isothermal lines for the temperatures 175°, 180°, 185°, 190°, and so on, at certain definite pressures, which may be read from a properly-constructed diagram. We can map the course of lines of equal volume, of which the instance given is one, using temperatures as ordinates and pressures as abscissæ. We can thus find the relations of temperature to pressure for certain definite volumes, which we may select to suit our convenience—say, 2 c.c. per gram; 3, 4, 5, 6, and so on. Now, all such lines are straight—that is, the relation of pressure to temperature, at constant volume, is one of the simplest; pressure is a linear function of temperature. Expressed mathematically—

$$p = bt - a,$$

where b and a are constants, depending on the volume chosen, and varying with each volume. But a straight line may be extrapolated without error; and so, having found values for a and b for such a volume as 6 c.c. per gram, by help of experiments at temperatures higher than 195°, it is possible by extrapolation to obtain the pressures corresponding to temperatures below the critical point 195° by simple means. But below that temperature the substance at volume 6 is in practice partly liquid and partly gas. Yet it is possible by such means to ascertain the relations of pressure to temperature for the *unrealizable portion* of the state of a liquid—that is, we can deduce the pressure and temperature corresponding to a continuous change from liquid to gas. And in this manner the sinuous lines on the figure have been constructed.

It is possible to realize experimentally certain portions of such continuous curves. If we condense all gaseous ether, and, when the tube is completely filled with liquid, carefully reduce pressure, the pressure may be lowered considerably below the vapour-pressure corresponding to the temperature of ebullition, without any change further than the slight expansion of the liquid resulting from the reduction of pressure—an expansion too small to be seen with this apparatus. But on still further reducing pressure, sudden ebullition occurs, and a portion of the liquid suddenly changes into gas, while the pressure rises quickly to the vapour-pressure corresponding to the temperature. If we are successful in expelling all air or gas from the ether in filling the tube, a considerable portion of this curve can be experimentally realized.

The first notice of this appearance, or rather of one owing its existence to a precisely similar cause, is due to Hooke, the celebrated contemporary of Boyle. It is noted in the account of the proceedings of the Royal Society on November 6, 1672, that "Mr. Hooke read a discourse of his, containing his thoughts of the experiment of the quicksilver's standing top-full, and far above the height of 29 inches; together with some experiments made by him, in order to determine the cause of this strange phenomenon. He was ordered to prepare those experiments for the view of the Society." And on November 13 "the experiment for the high suspension of quicksilver being called for, it was found that it had failed. It was ordered that thicker glasses should be provided for the next meeting."

There can be no doubt that this behaviour is caused by the attraction of the molecules of the liquid for each other. And if the temperature be sufficiently low, the pressure may be so reduced that it becomes negative—that is, until the liquid is exposed to a strain or pull, as is the mercury. This has been experimentally realized by M. Berthelot and by Mr. Worthington, the latter of whom has succeeded in straining alcohol at the ordinary tem-

Digitized by Google

perature with a pull equivalent to a negative pressure of 25 atmospheres, by completely filling a bulb with alcohol, and then cooling it. The alcohol in contracting strains the bulb inwards; and finally, when the tension becomes very great, parts from the glass with a sharp "click."

To realize a portion of the other bend of the curve, an experiment has been devised by Mr. John Aitken. It is as follows:—If air—that is, space, for the air plays a secondary part—saturated with moisture be cooled, the moisture will not deposit unless there are dust-particles on which condensation can take place. It is not at first evident how this corresponds to the compressing of a gas without condensation. But a glance at the figure will render the matter plain. Consider the isothermal 175° for ether, at the point marked A. If it were possible to lower the temperature to 160°, without condensation, keeping volume constant, pressure would fall, and the gas would then be in the state represented on the isothermal line 160°, at G: that is, it would be in the same condition as if it had been compressed without condensation.

You saw that a gas, or a liquid, is heated by compression; a piece of tinder was set on fire by the heat evolved on compressing air. You saw that condensation of ether was brought about by diminution of pressure—that is, it was cooled. Now, if air be suddenly expanded, it will do work against atmospheric pressure, and will cool itself. This globe contains air; but the air has been filtered carefully through cotton-wool, with the object of excluding dust-particles. It is saturated with moisture. On taking a stroke of the pump, so as to exhaust the air in the globe, no change is evident; no condensation has occurred, although the air has been so cooled that the moisture should condense, were it possible. On repeating the operation with the same globe, after admitting dusty air—ordinary air from this room—a slight fog is produced, and, owing to the light behind, a circular rainbow is seen; a slight shower of rain has taken place. There are comparatively few dust particles, because only a little dusty air has been admitted. On again repeating, the fog is denser; there are more particles on which moisture may condense.

One point more, and I have done. Work is measured by the distance or height through which a weight can be raised against the force of gravity. The British unit of work is a foot-pound—that is, a pound raised through one foot; that of the metric system is one gram raised through one centimetre. If a pound be raised through two feet, twice as much work is done as that of raising a pound through one foot, and an amount equal to that of raising two pounds through one foot. The measure of work is therefore the weight multiplied by the distance through which it is raised. When a gas expands against pressure, it does work. The gas may be supposed to be confined in a vertical tube, and to propel a piston upwards, against the pressure of the atmosphere. If such a tube has a sectional area of one square centimetre, the gas in expanding a centimetre up the tube lifts a weight of nearly 1000 grams through one centimetre; for the pressure of the atmosphere on a square centimetre of surface is nearly 1000 grams—that is, it does 1000 units of work, or ergs. So the work done by a gas in expanding is measured by the change of volume multiplied by the pressure. On the figure, the change of volume is measured horizontally, the change of pressure vertically. Hence the work done is equivalent to the area ABCD on the figure.

If liquid, as it exists at A, change to gas as it exists at B, the substance changes its volume, and may be made to do work. This is familiar in the steam-engine, where work is done by water, expanding to steam and so increasing its volume. The pressure does not alter during this change of volume, if sufficient heat be supplied, hence the work done during such a change is given by the rectangular area.

Suppose that a man is conveying a trunk up to the first story of a house, he may do it in two (or, perhaps, a greater number of) ways. He may put a ladder up to the drawing-room window, shoulder his trunk, and deposit it directly on the first floor. Or he may go down the area stairs, pass through the kitchen, up the kitchen stairs, up the first flight, up the second flight, and down again to the first story. The end result is the same; and he does the same amount of work in both cases, so far as conveying the weight to a given height is concerned; because in going down-stairs he has actually allowed work to be done on him, by the descent of the weight.

Now, the liquid in expanding to gas begins at a definite volume; it evaporates gradually to gas without altering pressure, heat being, of course, communicated to it during the change, else it would cool itself; and it finally ends as gas. It increases its volume by a definite amount at a definite pressure, and so does a definite amount of work; this work might be utilized in driving an engine.

But if it pass continuously from liquid to gas, the starting-point and the end point are both the same as before. An equal amount of work has been done. But it has been done by going down the area stair, as it were, and over the round I described before.

It is clear that a less amount of work has been done on the left-hand side of the figure than was done before; and a greater amount on the right-hand side; and if I have made my meaning clear, you will see that as much less has been done on the one side as more has been done on the other—that is, that the area of the figure BEH must be equal to that of the figure AFH. Dr. Young and I have tried this experimentally—that is, by measuring the calculated areas; and we found them to be equal.

This can be shown to you easily by a simple device—namely, taking them out and weighing them. As this diagram is an exact representation of the results of our experiments with ether, the device can be put in practice. We can detach these areas which are cut out in tin, and place one in each of this pair of scales, and they balance. The fact that a number of areas thus measured gave the theoretical results of itself furnishes a strong support of the justice of the conclusions we drew as regards the forms of these curves.

To attempt to explain the reasons of this behaviour would take more time than can be given to-night; moreover, to tell the truth, we do not know them. But we have at least partial knowledge; and we may hope that investigations at present being carried out by Prof. Tait may give us a clear idea of the nature of the matter, and of the forces which act on it, and with which it acts, during the continuous change from gas to liquid.

EXPERIMENTAL RESEARCHES ON MECHANICAL FLIGHT.

THE following is a translation of a communication made by Prof. S. P. Langley to the Paris Academy of Sciences on July 13:—

I have been carrying out some researches intimately connected with the subject of mechanical flight, the results of which appear to me to be worthy of attention. They will be published shortly in detail in a memoir. Meanwhile I wish to state the principal conclusions arrived at.

In this memoir I do not pretend to develop an art of mechanical flight; but I demonstrate that, with motors having the same weights as those actually constructed, we possess at present the necessary force for sustaining, with very rapid motion, heavy bodies in the air; for example, inclined planes more than a thousand times denser than the medium in which they move.

Further, from the point of view of these experiments and

Digitized by Google

also of the theory underlying them, it appears to be demonstrated that if, in an aërial movement, we have a plane of determined dimensions and weight, inclined at such angles and moving with such velocities that it is always exactly sustained in horizontal flight, the more the velocity is augmented the greater is the force necessary to diminish the sustaining power. It follows that there will be increasing economy of force for each augmentation of velocity, up to a certain limit which the experiments have not yet determined. This assertion, which I make here with the brevity necessary in this *résumé*, calls for a more ample demonstration, and receives it in the memoir that I have mentioned.

The experiments which I have made during the last four years have been executed with an apparatus having revolving arms about 20 metres in diameter, put in movement by a 10 horse-power steam-engine. They are chiefly as follows :—

(1) To compare the movements of planes or systems of planes, the weights, surface, form, and variable arrangements, the whole being always in a horizontal position, but disposed in such a manner that it could fall freely.

(2) To determine the work necessary to move such planes or systems of planes, when they are inclined, and possess velocities sufficient for them to be sustained by the reaction of the air in all the conditions of free horizontal flight.

(3) To examine the motions of aërostats provided with their own motors, and various other analogous questions that I shall not mention here.

As a specific example of the first category of experiments which have been carried out, let us take a horizontal plane, loaded (by its own weight) with 464 grams, having a length 0·914 metre, a width 0·102 metre, a thickness 2 mm., and a density about 1900 times greater than that of the surrounding air, acted on in the direction of its length by a horizontal force, but able to fall freely.

The first line below gives the horizontal velocities in metres per second; the second the time that the body took to fall in air from a constant height of 1·22 metres, the time of fall in a vacuum being 0·50 second.

Horizontal velocities ...	0m., 5m., 10m., 15m., 20m.
Time taken to fall from a constant height of 1·22 metres	0·53s., 0·61s., 0·75s., 1·05s., 2·00s.

When the experiment is made under the best conditions it is striking, because, the plane having no inclination, there is no vertical component of apparent pressure to prolong the time of fall; and yet, although the specific gravity is in this more than 1900 times that of the air, and although the body is quite free to fall, it descends very slowly, as if its weight were diminished a great number of times. What is more, the increase in the time of fall is even greater than the acceleration of the lateral movement.

The same plane, under the same conditions, except that it was moved in the direction of its length, gave analogous but much more marked results; and some observations of the same kind have been made in numerous experiments with other planes, and under more varied conditions.

From that which precedes, the general conclusion may be deduced that the time of fall of a given body in air, whatever may be its weight, may be indefinitely prolonged by lateral motion, and this result indicates the account that ought to be taken of the inertia of air, in aërial locomotion, a property which, if it has not been neglected in this case, has certainly not received up to the present the attention that is due to it. By this (and also in consequence of that which follows) we have established the necessity of examining more attentively the practical possibility of an art very admissible in theory —that of causing heavy and conveniently disposed bodies to slide or, if I may say so, to travel in air.

In order to indicate by another specific example the nature of the data obtained in the second category of my experiments, I will cite the results found with the same plane, but carrying a weight of 500 grams, that is 5380 grams per square metre, inclined at different angles, and moving in the direction of its length. It is entirely free to rise under the pressure of the air, as in the first example it was free to fall; but when it has left its support, the velocity is regulated in such a manner that it will always be subjected to a horizontal motion.

The first column of the following table gives the angle (*a*) with the horizon; the second the corresponding velocity (V) of *planement*—that is, the velocity which is exactly sufficient to sustain the plane in horizontal movement, when the reaction of the air causes it to rise from its support; the third column indicates in grams the resistances to the movement forward for the corresponding velocities—a resistance that is shown by a dynamometer. These three columns only contain the data of the same experiment. The fourth column shows the product of the values indicated in the second and third—that is to say, the work T, in kilogram-metres per second, which has overcome the resistance. Finally, the fifth column, P, designates the weight in kilograms of a system of such planes that a 1 horse-power engine ought to cause to advance horizontally with the velocity V and at the angle of inclination *a*.

	V	R	$T = \frac{VR}{1000}$	$P = \frac{500 \times 4554}{T \times 60 \times 1000}$
45 ...	11·2 ...	500 ...	5·6	6·8
30 ...	10·6 ..	275 ...	2·9	13·0
15 ...	11·2 ...	128 ...	1·4	26·5
10 ...	12·4 ...	88 ...	1·1	34·8
5 ...	15·2 ...	45 ...	0·7	55·5
2 ...	20·0 ...	20 ...	0·4	95·0

As to the values given in the last column, it is necessary to add that my experiments demonstrate that, in rapid flight, one may suppose such planes to have very small interstices, without diminishing sensibly the power of support of any of them.

It is also necessary to remark that the considerable weights given here to the planes have only the object of facilitating the quantitative experiments. I have found that surfaces approximately plane, and weighing ten times less, are sufficiently strong to be employed in flight, such as has been actually obtained, so that in the last case more than 85 kilograms are disposable for motors and other accessories. As a matter of fact, complete motors weighing less than five kilograms per horse-power have recently been constructed.

Although I have made use of planes for my quantitative experiments, I do not regard this form of surface as that which gives the best results. I think, therefore, that the weights I have given in the last column may be considered as less than those that could be transported with the corresponding velocities, if in free flight one is able to guide the movement in such a manner as to assure horizontal locomotion—an essential condition to the economical employment of the power at our disposal.

The execution of these conditions, as of those that impose the practical necessity of ascending and descending with safety, belongs more to the art of which I have spoken than to my subject.

The points that I have endeavoured to demonstrate in the memoir in question are :—

(1) That the force requisite to sustain inclined planes in horizontal aërial locomotion diminishes, instead of increasing, when the velocity is augmented; and that up to very high velocities—a proposition the complete experimental demonstration of which will be given in my memoir; but I hope that its apparent improbability

Digitized by Google

will be diminished by the examination of the preceding examples.

(2) That the work necessary to sustain in high velocity the weights of an apparatus composed of planes and a motor may be produced by motors so light as those that have actually been constructed, provided that care is taken to conveniently direct the apparatus in free flight; with other conclusions of an analogous character.

I hope soon to have the honour of submitting a more complete account of the experiments to the Academy.

ON THE SOLID AND LIQUID PARTICLES IN CLOUDS.[1]

IN this paper are given the results of some observations made while on the Rigi in May last, on the solid and liquid particles in clouds. It was noticed, when making observations on the number of dust particles in the atmosphere, that when the top of the mountain was in cloud, the number of particles varied greatly in short intervals; while previous experience had shown that at elevated stations the number was fairly constant for long periods. In order to investigate the case of this want of uniformity in the impurity of clouded air, extreme conditions were selected, and the air tested in cloud and in the clear air outside of it. When this was done the clouded air was found to have always more dust in it than the air outside. Its humidity was of course also greater. The relative amount of dust in pure and in clouded air varied greatly. Some parts of the cloud had only about double the number of particles there were in the clear air, while in other parts the proportion was much greater. The best example tested occurred on the 25th of the month, when there were observed 700 particles per c.c. in the clear air, while the number in cloud went up to over 3000, and in one cloud to 4200 particles per c.c. These observations were taken on the top of the mountain while the clouds were passing over it; the readings being taken in the cloud and again when it had passed and was replaced by clear air.

These observations at once showed the cause of the variability in the number of dust-particles in the clouds. The dust acted as a kind of ear-mark, and showed that the air forming the clouds was impure valley air, which had forced its way up into the purer air above. This impure air had become more or less mixed with the purer upper air. Where little of the impure air had mixed with the upper air, the number of particles was not large, and the clouding slight; but where the valley air was greatly in excess, the number of particles was great, and the clouding dense. It should be noted here that all the clouds tested were cumulus. It is quite probable that the conditions in stratus and other clouds may be different.

During this visit to the Rigi there were a number of opportunities of investigating the water particles in clouds. The apparatus used was the small instrument described to the Society in May last. With this instrument the water particles in clouds can be easily seen, and the number falling on a given area counted. The results are similar to those already communicated to the Society from observations made in fogs during last winter. On observing with this instrument in clouds, the water particles were distinctly seen showering down, and the number falling on the micrometer easily counted. The number of drops falling was observed to vary greatly from time to time. At times so quickly did they fall that it was impossible to count the number that fell on only 1 sq. mm. The greatest rate actually counted was 60 drops per sq. mm. in 30 seconds, but for a few seconds the rate was much quicker. Though the quick falls seldom lasted long, yet 30 drops per sq. mm. per minute were frequently observed for a considerable time. The maximum rate of 60 per sq. mm. per half minute gives 12,000 drops per square centimetre per minute, or 77,400 drops per square inch per minute. This does seem to be an enormous number of drops to fall on so small an area in the time. These drops, however, are so extremely small they rapidly evaporate, more than two or three being seldom visible at the same time on one square of the micrometer. The denser the cloud the quicker was the rate of fall, and as the cloud thinned away the drops fell at longer intervals, and they diminished in size at the same time.

It was frequently observed when the mountain-top was in clouds, particularly if they were not very dense overhead, that the surfaces of all exposed objects were quite dry; not only the stones on the ground, which might have received heat from the earth, but also wooden seats, posts, &c., were all perfectly dry, and if wetted they soon dried. While everything was dry, the fog-counter showed that fine rain-drops were falling in immense numbers. From the fact that the air was packed full of these small drops of water, it might have been assumed that the air was saturated, and tests with properly-protected wet and dry bulb thermometers showed that it was saturated. A few observations were therefore made to explain this apparent contradiction of surfaces remaining dry while exposed to a continued shower of fine rain and surrounded by saturated air. The explanation was found to be, simply, radiant heat. Though the cloud may be so dense, it is impossible to see the sun or even a preponderance of light in one direction to indicate its position; yet, as a good deal of light penetrates under these conditions, it therefore seemed possible some heat might do so also. A thermometer with black bulb *in vacuo* showed that a considerable amount of heat penetrated the clouds under the conditions, as it rose 40° to 50° above the temperature of the air while the observations were being made. This radiant heat is absorbed by all exposed surfaces and heats them, while they in turn heat the air in contact with them, and the fine drops of water are either evaporated in this hot layer of air or after they come in contact with the heated surfaces. Other observations made on Pilatus pointed to the same conclusion. All large objects, such as seats, posts, &c., were quite dry in cloud when there was any radiation; while small objects, such as pins, fine threads, &c., were covered with beads of water. The large surfaces being more heated by radiation than small ones, when surrounded by air, these surfaces evaporate the drops falling on them, while the small ones, being kept cool by the passing air, are unable to keep themselves dry.

The observations made with the fog-counter point to the conclusion that the density or thickness of a cloud depends more on the number of water particles than on the number of dust particles in it. The number of the dust particles in the clouds varied too much and too quickly to enable any conclusion to be drawn from observations made in clouds themselves. However, on comparing the thickness of a cloud on the Rigi and a fog at low level, when the number of water-drops was about the same, it is found that the fog, though thicker, was not greatly so, although there were only a few thousand dust-particles per c.c. in the cloud, while there were about 50,000 in the fog.

The observations with the fog-counter show that, whenever a cloud is formed, it at once begins to rain, and the small drops fall into the drier air underneath, where they are evaporated, the distance to which they will fall depending on their size and the dryness of the air. It is thought that much of the dissolving of clouds is brought about in this way.

[1] Abstract of Paper read before the Royal Society, Edinburgh, on July 6, by John Aitken, F.R.S. Communicated by permission of the Council of the Society.

OLD STANDARDS.

BY a curious accident it has just been discovered that the standard yard and certain other measures and weights which were supposed to have been lost when the Houses of Parliament were destroyed by fire in 1834 are still in existence. The following account of the matter is condensed from a statement in the *Times*. A reference to the contemporary records shows that after the fire the standard bars of 1758 and 1760 were both found among the ruins, "but they were too much injured to indicate the measure of a yard which had been marked upon them." The principal injury to both of the standards was the loss of the left-hand gold stud, but whether this was caused by the action of the flames or otherwise is not known. When the Palace of Westminster was rebuilt the two bars were deposited in the Journal Office, and from that time, until the other day, they seem to have been wholly lost sight of. About a fortnight ago it happened to be stated in the lobby that one of the duties of the Speaker was to inspect once in every twenty years the standards immured in the sill of the Lower Waiting Hall. Inquiries at the Standards Department of the Board of Trade elicited the fact that, so far from any statutory requirement being imposed upon the Speaker in the direction indicated, Section 35 of the Weights and Measures Act, 1878, which provides for the care and restoration of the Parliamentary copies of the Imperial standards, specially exempts the walled-up copy from periodical inspection and comparison. It was found, however, that in 1871 Speaker Denison took cognizance of the standards; and this fact was brought to the Speaker's notice. While inquiries were being made as to Speaker Denison's inspection, an official in the Journal Office mentioned that when the contents of that office were recently being transferred to the new wing he had observed among the lumber some old weights and measures. These proved to be the missing standards. On Tuesday last they were examined by Mr. Chaney, the Superintendent of Weights and Measures; and on Wednesday the Speaker was to visit the Journal Office for the purpose of inspecting them.

The most important of the standards thus rescued from oblivion are the yard measures constructed by Bird in 1758 and 1760. The former was copied from a bar in the possession of the Royal Society, which was itself a copy of a standard preserved in the Tower; and the second was constructed under the directions of a Committee of the House of Commons from the 1758 standard. "Each of these two standard yards consisted of a solid brass bar 1·05 in. square in section and 39·73 in. long. Near each end of the upper surface gold pins or studs 0·1 in. in diameter were inserted, and points or dots were marked upon the gold to determine the length of the yard." The other standards in the custody of the Journal Office are two brass rods answering the description of the old Exchequer yard, and four weights supposed to be certain of the "copies, model, patterns, and multiples" ordered by the House on May 21, 1760, "to be locked up by the clerk and kept by him." The most important weight—the standard troy pound—is not amongst those now brought to light.

NOTES.

AT some little distance to the north and north-east of Cardiff lies a beautiful piece of hilly country, much frequented by pedestrians, and known as the Black Mountain or Black Forest district. It has not been found practicable by the Local Committee to arrange an official excursion to this district on the occasion of the visit of the British Association to Cardiff; but a project is now being unofficially forwarded for conducting small parties of not exceeding six visitors each to some of the choicest parts of this country, at a time so arranged as not to interfere with the sittings of the various Sections. Several local gentlemen, thoroughly familiar with the district, have offered to act as guides, and with fair weather most enjoyable excursions are to be anticipated. The country being essentially one for pedestrians, the excursions would take the form of an afternoon walk of from eight to twelve miles, with a further walk on the following day of from twenty-five to thirty miles. Any member of the British Association desirous of taking part in one of these excursions can obtain full particulars by applying to the Local Secretaries, 9 Bank Buildings, Cardiff, who will forward the applications to the promoters.

THE annual meeting of the French Association for the Advancement of the Sciences will be held at Marseilles, commencing on September 17. The special subject chosen for discussion in the Botanical Section is the best mode of arrangement and exhibition for different kinds of botanical collections, with the double purpose of the preservation of the specimens and the facilitating of study.

THE Technical and Recreative Institute established by the Goldsmiths' Company at New Cross was opened by the Prince of Wales on Wednesday. In addition to this Institute there are to be two Polytechnics south of the Thames, one in Battersea Park Road, the other in the Borough Road. The memorial stone of the one in Battersea was laid by the Prince of Wales on Monday.

PROF. M. W. HARRINGTON, the founder of the *American Meteorological Journal*, has been appointed Chief of the United States Weather Bureau, under the Department of Agriculture in Washington. Prof. Harrington was born in Illinois in 1848, and graduated at Michigan in 1868. In 1879 he was made Professor of Astronomy and Director of the Astronomical Observatory at Ann Arbor, Michigan. From a recent article by him, entitled "How could the Weather Service best promote Agriculture?" it appears likely that the energies of the new service will be devoted more to the interests of agriculture than to commerce, and that an attempt will be made to issue special weather predictions for the farmer, by means of the multiplication of local forecasting stations. There can be little doubt—seeing the large amount of funds under his control—that he will also still further advance the important work of international meteorology which has been so ably conducted by his predecessors.

THE half-yearly general meeting of the Scottish Meteorological Society was held in Edinburgh on Wednesday. The report from the Council of the Society was presented; and papers were read on certain relations of wind, pressure, and temperature at the Ben Nevis Observatories, by Dr. Buchan, and on influenza and weather of London in 1891, by Sir Arthur Mitchell and Dr. Buchan.

FROM the official record of the work done in the British Museum during 1890 it seems that there has been a serious decrease in the number of visitors. Special departments, however, have been used more than ever by students; and it is satisfactory to find that the zoological and geological collections in the Natural History Museum are being more generally appreciated.

GERMAN scientific papers record the death, on June 18, of Dr. Otto Tischler, well known as an archæologist of wide learning and sound judgment. He especially distinguished himself by his investigation of the burial-mounds of East Prussia. Dr. Tischler was forty-eight years of age.

PROF. A. RICCÒ, Director of the Catania Observatory, who has just returned from a visit to the volcano Stromboli, sends us the following notice of a recent eruption:—"On June 24, 45

Digitized by Google

minutes after noon (Rome mean time), the inhabitants of the Æolian Isles were alarmed by two strong shocks of earthquake, followed by two tremendous explosions of the volcano, which sent forth from four mouths a great quantity of smoke, cinders, incandescent blocks, and currents of lava that descended the mountain slopes to the sea. The sea, at the points where the lava entered it, steamed up, producing great noisy masses of vapour. The phenomena continued till July 1. Stromboli has now returned to its habitual state of moderate activity."

THE annual meeting of the Society for the Preservation of the Monuments of Ancient Egypt was held last week in the rooms of the Society of Antiquaries at Burlington House. Lord Wharncliffe, President, occupied the chair. The report stated that there was little to report of success attending the proceedings of the Society for the past year. Its energies had been directed principally to two points—the necessity for an official inspector or superintendent in Egypt, whose duty should be the care of the ancient monuments, and an endeavour to do something towards arresting the gradual destruction of the Great Temple at Karnak. Reports concerning a proposed scheme for barring the Nile below Philæ, to make a vast reservoir for purposes of irrigation, had appeared in the public papers from time to time, and recently various more definite communications had been received by the committee on the same subject. The result would be, it was acknowledged, to completely cover this beautiful island and temple with water. There had been some correspondence on this subject with the authorities in Egypt; but as nothing had as yet been decided as to any scheme of irrigation, and as a committee would be appointed to consider the whole question, it might be considered as suspended for the present, and the committee had thought it best to wait before taking any further action; but they would not lose sight of this important matter, and would oppose to the utmost of their power any engineering scheme which would involve injury or destruction to this world-renowned spot. General Donnelly moved the adoption of the report; and the motion was seconded by Sir Edmund Henderson, and agreed to. The committee for the coming year was then elected, and a discussion subsequently took place as to the proposed scheme for barring the Nile below Philæ, the opinion of the meeting being evidently strongly opposed to the adoption of any system of irrigation which should involve damage to the temple. Mr. J. Bryce, M.P., spoke of the wanton injury which was often inflicted on monuments in Egypt, and said that he thought it would be necessary, in dealing with that matter, to bring the question of jurisdiction to the attention of those from whom any system of inspection or care was to emanate. We may note that in answer to a question put by Mr. Bryce in the House of Commons on July 15, Sir J. Fergusson said that nothing definite had been settled as to the preservation of ancient monuments in Egypt; £E10,000 had been allotted in the Budget for the current year.

THE Pilot Chart of the North Atlantic Ocean for July contains a special account of a hurricane that moved along a track almost due north, about 500 miles east of Newfoundland on June 9 and 10, together with a chart of the conditions of barometer and wind between Newfoundland and Ireland, showing that the abnormal track was due to the approach of an anticyclone west of the British Isles. A supplement issued with the Pilot Chart illustrates the drift of every bottle paper returned to the United States Hydrographic Office since April 1889. There are 113 papers that contain the date of commencement and end of journey; the average number of miles that each bottle drifted is 869, and the average daily drift is 5·8 miles. This figure is rather below the true average rate per day, as any time the bottle lay upon the shore before discovery added to its time of drift.

M. PATOUILLARD has just returned from a scientific mission with which he was intrusted by the Minister of Public Instruction in France, an investigation of the mycological flora of Tunis, Carthage, and the adjacent regions.

IN one of the principal articles of the *Meteorologische Zeitschrift* for May, Herr R. Börnstein discusses the question of a connection between air-pressure and the hour angle of the moon, using as a basis the hourly observations of four German and Austrian stations. This investigation differs from the usual mode of treatment, as it takes no account of the moon's phases, or of its declination or distance from the earth, but only of the lunar day, and deals solely with atmospheric pressure. The results arrived at are: (1) that the existence of atmospheric tides is not plainly recognizable in the range of pressure; (2) at three of the stations the pressure exhibits a single oscillation during the lunar day. The maximum occurs at Hamburg and Berlin shortly before the setting of the moon, and at Vienna about the time of the lower culmination, while the minimum occurs at all stations near the time of the moon's rising.

WE have received vol. viii. of the *Anales de la Oficina Meteorologica Argentina*. It contains a summation of the records obtained at five different stations in the Republic during the years 1877-89. The organization of the Department appears to be now very complete, there being no less than twenty-eight stations fully equipped with ordinary and self-registering instruments.

REFERRING to a statement which has been publicly made, that the adoption of electric lighting in place of gas at the office of the Savings Bank Department of the General Post Office has been followed by a marked reduction in the amount of sick leave, the *Lancet* says it has good authority for believing that the statement in question is substantially correct. Although the time which has as yet elapsed—two years—since the introduction of the new illuminant has been insufficient for the collection of trustworthy statistics, our contemporary thinks there is every reason to believe that electric lighting will prove to be much more wholesome than ordinary gas flames. An electric lamp does not compete for the oxygen of the apartment in which it is placed, and this circumstance gives it a marked advantage over any open flame. It cannot, like some forms of gas-burner, be used to promote ventilation; but in ordinary situations its harmlessness is a much more important property.

METEOROLOGICAL observatories are generally ill adapted, by reason of dust and smoke, for observations on atmospheric electricity; and, with the view of inciting private individuals to such work, Herren Elster and Geitel, of Wolfenbüttel, have lately issued a *brochure* in which they indicate the ends to be sought and the instrumental means. Three things demand attention: first, systematic observation and measurement of electricity in the open air at different times in the day and in the seasons, humidity and air-temperature being determined at the same time; second, measurement of the fall of potential with a clear sky; and third, measurement of the fall of potential and its change of sign during rain, &c. The instruments and methods recommended are such as present little difficulty for private persons.

THE American National Geographic Society prints in the current number of its magazine a full and interesting account, by Israel C. Russell, of an expedition to Mount St. Elias, Alaska. The paper is illustrated by various excellent maps and diagrams.

THE Winchester College Natural History Society has just issued, under the title of "Geological Notes" (J. Wells, Winchester), a list of all the fossils as yet known from the chalk in the anticlinal of Winchester. The exact localities and zones are given; and, since the names appear not only to have been

Digitized by Google

carefully determined, but to be well up to date, this very modest pamphlet will prove as useful a guide to the collector as it is valuable to the stratigraphical geologist.

MESSRS. WOODALL, MINSHALL, AND CO., Oswestry, have issued "A Flora of Oswestry and District," by T. P. Diamond, Honorary Secretary of the Offa Field Club. It contains a list of plants in the neighbourhood of Oswestry, arranged according to their natural orders; and at the end there is an index, in which both the English and the Welsh names of the plants are given. Mr. Diamond calls attention to the fact that his "list of over 700 plants includes representatives of 90 out of the 101 natural orders in the flora of the United Kingdom."

THE United States Department of Agriculture is printing—in the series entitled "Contributions from the United States National Herbarium"—what promises to be a valuable manual of the plants of Western Texas, by John M. Coulter. This district is described as "one of the richest regions in plant display, containing a flora particularly interesting on account of the intermingling of Mexican species." The manual is being published in parts because the author hopes that their successive appearance may call forth additional information that may be embodied in a final supplement.

A SHEET dealing with the potato disease will shortly be issued by the Royal Agricultural Society of England. It was originally published by the Irish Land Commission, by whose permission it is being reproduced. In the text, by Mr. William Carruthers, F.R.S., all necessary information is given, and this is accompanied by coloured drawings illustrating various phases of the potato disease.

IN the July number of the *London and Middlesex Note-Book*, Mr. G. F. Lawrence says he recently obtained a drift implement of unusual form from the site of Mr. Peter Robinson's new premises in Oxford Street. The peculiarity consists of the curious curvature of one face of the implement compared with the flatness of the other side. He does not know of another like it, but suggests that, as attention is called to what may be a mere variation of an ordinary type, examples may be found in other collections. This specimen is of a somewhat ochreous colour, is lustrous and but slightly abraded or rolled, and it measures 5⅝ inches long by 3 inches wide. The occurrence of drift-implements in Central London is rather unusual. Mr. Lawrence thinks twelve would be rather over than under the number known.

IN the current number of the Scientific Proceedings of the Royal Dublin Society (vol. vii. Part 2) Mr. E. W. L. Holt publishes a preliminary note on the fish obtained during the cruise of the s.s. *Fingal*, 1890, on the Society's survey of fishing grounds on the west coast of Ireland. Amongst the shore fishes, *Aphia pellucida*, Nardo, and *Crystallogobius nilssonii*, Düb. and Kor., are for the first time recorded from Irish waters. The second British specimen of *Arnoglossus grohmanni*, Bonap., is also recorded. From depths between 100 and 500 fathoms off Achill Head, *Pomatomus telescopium*, Risso, *Mora mediterranea*, Risso, and *Macrurus æqualis*, Gthr., are added to the British fauna; and a description is given of a new deep-sea eel, intermediate between Saurenchelys and Nettastoma, which has been named *Nettophichthys retropinnatus*, n. g. et sp. *Gadus esmarkii*, Nilsson, and *Macrurus rupestris*, Gunner, are added to the Irish fauna from similar depths, and *Argentina sphyræna*, Linn., from 52 to 80 fathoms. Amongst other fish recorded from depths exceeding 100 fathoms are *Chimæra monstrosa*, Linn., *Trigla lyra*, Linn., *Gadus argenteus*, Guich., *Phycis blennioides*, Brünn., *Haloporphyrus eques*, Gthr., *Macrurus cœlorhynchus*, Risso, *M. lævis*, Lowe, &c. A young Phycis is also recorded from 26 fathoms, and mention is made of the occurrence at the surface of a shoal of young *Gadus poutassou*, Risso, 34 miles from land.

HARDNESS is one of the most important properties of solid bodies; yet the measurement of it has not been very satisfactorily effected hitherto. Prof. Auerbach, of Jena, has recently described (*Repertorium für Physik*) an apparatus for the purpose, designed for transparent bodies. In it the spherical surface of a lens is pressed up by the short arm of a weighted lever against a small thick plate, on which the observer looks down through a microscope furnished with a micrometer, watching the effects of increasing pressure. Glass and rock crystal were observed. The author offers a theory of the subject, and tests it. A comparison of hardnesses with moduli of elasticity shows that, while the more elastic of those substances were also the harder, the hardness increases less than the elasticity.

FROM recent accounts it appears that the consumption of gas in Paris in 1890 exceeded that in 1880 by 26·2 per cent., while the number of consumers increased 56·8 per cent. The amount per consumer diminished 19·5 per cent., from 1642 to 1322 cubic metres. Electricity has evidently withdrawn many large consumers of gas. The same account states that in *three* years the number of arc and glow lamps has increased 140 and 170 per cent. respectively. The consumption of petroleum in France has increased 47 per cent in those ten years, while that of gas, in the whole of France, has grown 62 per cent.

A SERIES of addition compounds of aldehydes with hypophosphorous acid are described by M. Ville in the current number of the *Annales de Chimie et de Physique*. As is well known, aldehydes exhibit the characteristic property of uniting directly with many other substances, such as ammonia, hydrocyanic acid, acid sulphites, and hydroxylamine. Some time ago, it was shown by Fossek that trichloride of phosphorus was likewise capable of uniting directly with many aldehydes with production of liquid compounds decomposable by water. M. Ville now shows that a similar series of additive compounds are formed with hypophosphorous acid, and these compounds are of considerable importance as throwing more light upon the nature of this lower acid of phosphorus. Hypophosphorous acid, H_3PO_2, the acid derived from the as yet unisolated oxide P_2O, may be regarded as possessing the structure $\begin{matrix} & H & \\ & | & \\ & PO-OH & \\ & | & \\ & H & \end{matrix}$. By the direct action of aldehydes under the influence of a slight rise of temperature, two distinct classes of new compounds are obtained. When the aldehyde and hypophosphorous acid are allowed to react in the proportion of equal molecules, compounds of the type $\begin{matrix} R-CH-OH \\ | \\ PO-OH \\ | \\ H \end{matrix}$ are obtained, where R may represent the radicle of any aldehyde. If, however, two molecular proportions of aldehyde are employed, compounds of the type $\begin{matrix} R-CH-OH \\ | \\ PO-OH \\ | \\ R-CH-OH \end{matrix}$ are formed. The aldehydes of the aromatic series lend themselves best to the formation of these compounds, those of the fatty series exhibiting a great tendency to the production of condensation products. The compound of the second type with benzoic aldehyde, $\begin{matrix} C_6H_5-CH-OH \\ | \\ PO-OH, \\ | \\ C_6H_5-CH-OH \end{matrix}$ is obtained by digesting to-

Digitized by Google

gether for several hours upon a water-bath benzaldehyde and hypophosphorous acid in an atmosphere of carbon dioxide. Crystals of the new compound soon commence to separate, and rapidly permeate the whole liquid. On draining and washing, they are found to consist of colourless radiating groups of lamellæ. They are not very soluble in water, but dissolve more readily in organic solvents, best in methyl alcohol. The aqueous solution is strongly acid, decomposing carbonates readily, and forming crystalline salts with bases. Curiously, though, it exerts no reducing action upon solutions of copper sulphate or silver salts.

In order to obtain the acid of the first type,

$$\begin{array}{l} C_6H_5—CH—OH \\ \qquad\qquad\quad | \\ \qquad\qquad PO—OH, \\ \qquad\qquad\quad | \\ \qquad\qquad\quad H \end{array}$$

it is best to employ an excess of hypophosphorous acid. In this case, instead of crystals of the acid of the second type separating, the whole forms a homogeneous liquid which remains unprecipitated by water. It contains the acid of the first type, and this latter is best isolated by precipitating the lead salt by the addition of lead acetate and decomposing the salt, suspended in water, by means of sulphuretted hydrogen. On concentration of the filtered solution, a syrup is obtained which eventually yields deliquescent crystals of the pure acid. The solution of this acid does not reduce copper sulphate, but readily precipitates metallic silver from silver nitrate. Many similar compounds with other aldehydes have also been prepared, and found to present analogous properties more or less modified by the specific nature of the particular aldehyde employed.

THE additions to the Zoological Society's Gardens during the past week include two Ruddy-headed Geese (*Bernicla rubidiceps* ♂ ♂) from the Falkland Islands, presented by Mr. F. E. Blaauw, C.M.Z.S.; a Smooth Snake (*Coronella lævis*), British, presented by Mr. W. H. B. Pain; two great Eagle Owls (*Bubo maximus*), European, deposited; six Eyed Lizards (*Lacerta ocellata*), two Four-lined Snakes (*Coluber quadrilineatus*), a Back-marked Snake (*Rhinechis scalaris*), South European, purchased; a Burrhel Wild Sheep (*Ovis burrhel* ♂), a Japanese Deer (*Cervus sika* ♀), a Bennett's Wallaby (*Halmaturus bennetti* ♀), two Night Herons (*Nycticorax griseus*), bred in the Gardens.

OUR ASTRONOMICAL COLUMN.

A CAUSE OF LUNAR LIBRATION.—A paper by Mr. S. E. Peal, "On a Possible Cause for Lunar Libration other than an Ellipsoidal Figure, and on Lunar Snow Mountains," has recently been published by Messrs. Dulau and Co. It is shown that evidence of several kinds points to the existence of a vast shoal, or submerged continent, some 1500 miles long by 400 across along the prime meridian. This is presumed to be of greater specific gravity than the refrigerated *maria* east and west of it, and to have been at one time situated in the southern hemisphere. The difference of attraction upon the shoal and the surrounding *maria* is shown to be sufficient both to cause and maintain libration. Since libration began, the shoal has placed itself geocentrically, in which case the south pole must have been drawn forward about 30°. The possibilities of the case seem to be as follows. The moon formerly had a physical constitution the same as that of the earth at the present time. The lunar ocean beds were then steadily subsiding, the lines of upheaval and weakness being on the continents, and causing a series of *quasi*-volcanic orifices. Whilst tidal friction was reducing the velocity of rotation, polar snow-caps were formed, and the atmosphere became rarer. The extension of the snow-cap to the equator was for ages prevented by the incidence of solar heat. This struggle between steadily-increasing refrigeration and solar heat should therefore be evidenced by the existence of an irregular belt about the (then) equator. Such a belt is found in the circular *maria* Smythii, Crisium, Serenitatis Imbrium, and part of Oceanus Procellarum. If the axis of rotation be shifted about 30°, so that the south pole occurs near Nach or Maginus, all these irregular *maria* form a chain of seas along the equator, which may represent the belt of solar influence referred to. Eventually these *maria* were refrigerated, and the meridional shoal, acting as a fixed tide during libration, caused the change in the direction of the axis of rotation, which shifted the belt of seas from their equatorial position to that at present occupied by them.

DOUBLE-STAR OBSERVATIONS.—In *Astronomische Nachrichten*, Nos. 3047 and 3048, Mr. S. W. Burnham gives the results of his double-star observations made in 1890 with the 36-inch equatorial of the Lick Observatory. The stars which have been re-observed are mainly those which cannot easily be measured on account of their being beyond the reach of any but the most powerful telescopes. Mr. Burnham also notes that his purpose has not been to find as many pairs as possible without reference to their character, but to make several measurements of interesting ones. The present catalogue of new stars contains 70 pairs, of which 39 have distances less than 1″, with an average distance of 0″·45.

The following naked-eye stars are included in the list of new binaries:—B.A.C. 230, 48 Cephei (H), 5 Camelopardus, τ Herculis, Ceti 199, 34 Persei, ν Geminorum, 24 Aquarii, 95 Piscium, B.A.C. 1142, 36 Geminorum, ψ^1 Aquarii, χ Persei, Tauri 148, 65 Geminorum; and the following pairs, previously known, have been found to be more closely double:—H 1981, S 409, Σ 809, OΣ (app.) 77, Σ 2476, OΣ 425, Σ 12 (app. II.).

OBSERVATIONS OF THE ZODIACAL COUNTER-GLOW.—An account of observations of the zodiacal counterglow, or *Gegenschein*, made at Mount Hamilton from 1888 to 1891, is contributed to the *Astronomical Journal*, No. 243, by Mr. E. E. Barnard. The changes of form previously noted have been confirmed. In the fall of the year the *Gegenschein* appears large and roundish. It afterwards becomes elongated, and connected with the zodiacal light by a narrow zodiacal band. The observations prove that the *Gegenschein* does not lie in the ecliptic, although very nearly so. Neither is it exactly 180° from the sun. The mean of sixteen observations assign the following longitude and latitude to the phenomenon:—

$$\odot - \lambda = 180°{\cdot}6\,;\ \beta = +1°{\cdot}3.$$

THE OBSERVATORY OF YALE UNIVERSITY.—The Report for the year 1890–91 of the Observatory of Yale University contains a report from Dr. Elkin, from which we make the following extracts:—

"In observational work with the heliometer I have been engaged almost wholly in the continuation of the series on the parallaxes of the first magnitude stars in the northern hemisphere. The scheme originally laid out has now been completed, and furnishes for each of the ten stars three (for Arcturus five) independent results.

"The triangulation of the comparison stars for Victoria according to the plan drawn up by Dr. Gill has been carried out by Mr. F. L. Chase, who secured some 450 measures of these stars during the months of June to October 1890. Mr. Chase has also reduced the observations as far as it was advisable for us to do so here, and the results have been communicated to Dr. Gill, along with the reduced results of our observations of Victoria and Sappho in 1889. Since February 1891, Mr. Chase has been engaged in a triangulation of the principal stars in *Coma Berenices*, and up to date about one-half of the proposed measures have been obtained.

"It is proposed during the ensuing season to devote the heliometer to a series of measures on the satellites of Jupiter for the determination of their orbits and the mass of the planet, comparing them *inter se*, as has been done with such success by Hermann Struve at Pulkova with those of Saturn."

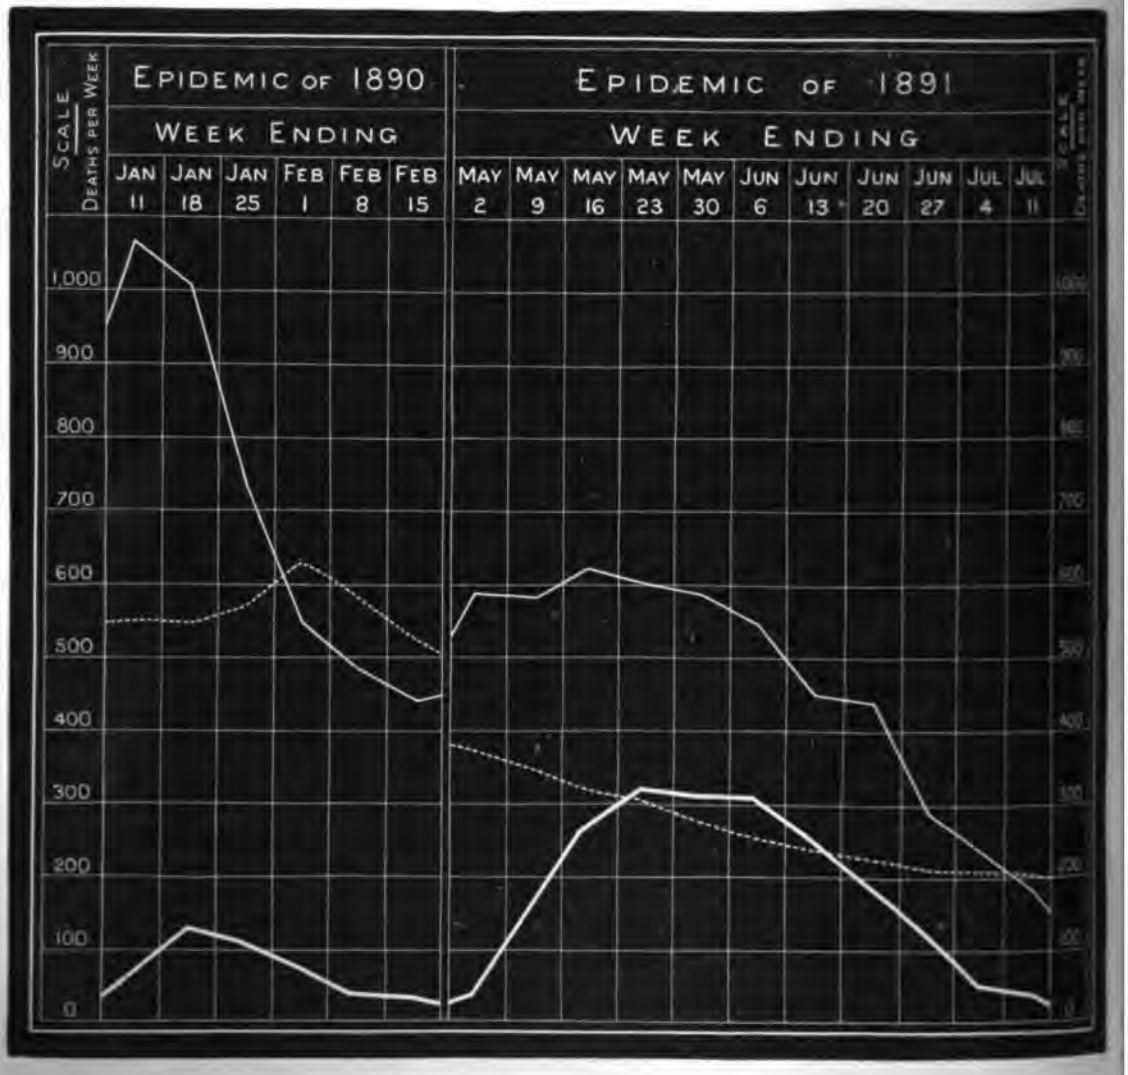
THE RECENT EPIDEMIC OF INFLUENZA.

THE mortality in London from influenza shows a steady decline week by week; and, although the number of deaths is still in excess of the average, there are good reasons for hoping that the epidemic will shortly disappear from our midst. The severity of the recent visitation, as compared with that which prevailed last year, is clearly shown by the accompanying diagram, in which the effects of the two epidemics are displayed side by side. The weekly mortality from influenza alone is represented by the thick curve, the number of deaths

Digitized by Google

from diseases of the respiratory system by the lighter curve, and the average number of deaths from disorders of the latter class by a dotted line. The average mortality from influenza is too small to permit of any curve being drawn upon the scale shown in the diagram.

Taking into consideration, firstly, the mortality from influenza alone, we find that not only was the duration of last year's epidemic far less than that of the present year, but that the number of deaths in the earlier period was very much smaller than in the latter. The epidemic of 1890 set in with great severity and suddenness at the beginning of January. During the week ending December 28, 1889, there were no deaths in



London from this disease, and in the following week only 4. In the week ending January 11, 1890, however, the number had risen to 67, while in the course of the ensuing seven days a maximum of 127 was reached. The mortality then declined steadily, the numbers in the four succeeding weeks being respectively, 105, 75, 38, and 30. As a serious epidemic the visitation may then be regarded as having spent itself, and in preparing the diagram I have not considered it advisable to include any period in which the weekly number of deaths fell below 25. It may, however, be remarked that, for three weeks [illegible] by the curve, the mortality exceeded [illegible] preceding weeks it ranged between 10 [illegible] whole the period of six weeks in which

the epidemic prevailed with more or less severity, it appears that the total number of deaths in London was 442, giving an average of 74 per week.

The visitation of the present year may be said to have commenced at the beginning of May. During the whole of April there were a few deaths from influenza, the numbers in the four weeks embraced by the Registrar-General's returns being respectively 7, 3, 9, and 10. By the week ending May 2, however, the number had risen to 37, and from this time onward the disease continued to spread with alarming rapidity, the numbers in the three successive weeks being 148, 266, and a maximum during the week ending May 23 of 319. In the two following weeks the mortality again exceeded 300, after which it declined steadily to 249, 182, 117, and 56, while in the last period shown by the diagram the number had fallen to 41. Taking the period as a whole, it appears that during the eleven weeks ending July 11 the total number of deaths in London from influenza, irrespective of cases in which it was known to have been present in the course of other diseases, was 2,033, giving an average of 184 per week, or about two and a half times as much as the average mortality in 1890. In no fewer than seven weeks out of the eleven the number of deaths exceeded the maximum attained during the epidemic of the year.

From an examination of the statistics given, it is evident

Digitized by Google

paper read before the Scottish Meteorological Society on March 31, 1890, by Sir Arthur Mitchell and Dr. Buchan (an abstract of which appeared in NATURE, vol. xli. p. 596), it is quite evident that the recent epidemic of influenza has been the most severe we have had in London since the first publication of weekly records of mortality some forty-five years ago. As the figures are of great interest, we make no apology for reproducing the brief table given in that paper, showing the number of deaths which occurred in the five principal epidemics experienced since the year 1847. It will be observed that the number given for last year is considerably in excess of that quoted above, the period selected by the authors of the paper comprising the whole of the three months January to March. In the month last mentioned, the epidemic was certainly not of any great severity, but as the figures do not clash in any way with the general argument, I have not thought it advisable to alter the results. An addition has, however, been made to the table, by including the figures of mortality reached during the epidemic of the present year.

	Deaths.
December 1847 to April 1848	1631
March to May 1851	258
January to March 1855	130
November 1857 to January 1858	123
January to March 1890	545
May to July 1891	2027

It will be seen from the table that the mortality recently experienced has been far greater than at any other period during the forty-five years, the nearest approach to so severe an epidemic being in 1847–48, when the deaths amounted to about 400 less. Taking into consideration the fact that the population of London 45 years ago was very much smaller than it is now, it may at the first blush appear that, as regards severity, there was not very much to choose between the two visitations. It must not be forgotten, however, that in the earlier period the ravages of the disease extended over five months, while in the latter they were confined to about two and a half.

A very striking feature in the disease to which the somewhat misleading name of influenza has been given, is its peculiarly weakening effect upon the lungs and bronchial tubes; and as the epidemic is invariably attended by a high mortality from respiratory diseases, I have included in the diagram a series of curves showing the number of deaths from these attendant disorders. As regards the epidemic of 1890, it may at once be confessed that the curve is somewhat misleading. During the last few days of 1889 and the opening of the following year a sharp touch of anticyclonic cold was experienced over England; and in the metropolis this was accompanied, as is so commonly the case, by thick fog. Under such circumstances a high mortality from respiratory diseases followed as a matter of course, so that when we examine the curve we find that, at the time when the epidemic of influenza was only just appearing, the deaths from lung disorders were at their maximum. After the first week in January, however, the weather became unusually mild for the time of year, a long period of south-westerly winds setting in, with abnormally high temperatures. There can be little doubt, in fact, that at the time the influenza epidemic of 1890 was raging the effects of temperature and weather were so strong as to obliterate the influences of the miasmatic disorder upon diseases of the respiratory system. This year, however, the meteorological element may almost be eliminated from account, for, although cold winds were very frequent in May and the early part of June, the severity of the weather was not such as to lead to any material increase of mortality from the class of diseases in question. The spread of influenza was, however, soon followed by a serious rise in the death-rate, and in the course of the fortnight ending June 6 the mortality from respiratory complaints amounted to more than twice the average, the large excess being due chiefly to deaths from pneumonia and bronchitis. The subsequent decline of influenza was accompanied, as will be seen from the curve, by a corresponding decline of fatalities from respiratory diseases, but it was not until the last week of the period that the deaths fell short of the average. Taking the eleven weeks as a whole, it appears that the total mortality from respiratory disorders amounted to 5138, or about 75 per cent. more than the average. During the epidemic of 1890 the actual number was far larger, but in the winter months the average is also very much higher, and as a matter of fact the excess above the normal only amounted last year to 26 per cent.

The influence of the weather upon the two epidemics seems to have been exerted in entirely opposite directions. During the epidemic of 1890 temperature was, as we have already seen, for the most part very high for the time of year, and the prevalence of a strong current of south-westerly winds in January doubtless aided in the dispersal of the miasmatic germs. The weather was, in fact, as favourable as could have been desired, and the ravages of the epidemic, severe though they were, were doubtless much milder than they would have been had the winter been cold and foggy. The recent epidemic has not had so many foes to contend with, for in the earlier stages of its career the weather was not only cold for the time of year but also calm and quiet. The germ was therefore able to settle in our midst without serious opposition, and the ungenial nature of the atmosphere has doubtless been responsible for much of the lung and bronchial disease which has followed in its train. Deluded by the knowledge that the spring season was upon us, and forgetful of the fact that it had come in an unkindly guise, many a weakly convalescent has been emboldened to venture out into the chilly air, and has contracted a serious cold, from which in too many cases he has been unable to recover. FREDK. J. BRODIE.

THE MUSEUMS ASSOCIATION.

THE Museums Association held its second annual meeting in Cambridge on July 7, 8, and 9, under the presidency of Mr. John Willis Clark, Superintendent of the Museum of Zoology and Comparative Anatomy, Cambridge, and Registrary of the University.

The following representatives of Museums (outside Cambridge) and associates were present:—The Rev. H. H. Higgins, Mr. R. Paden (Liverpool); Mr. R. Cameron, Mr. J. M. E. Bowley (Sunderland); Mr. G. B. Rothera, Mr. J. W. Carr (Nottingham); Mr. Councillor P. Burt, Mr. J. Paton (Glasgow); Mr. T. W. Shore (Southampton); Lieut.-Colonel Turner, Mr. J. Tym (Stockport); Alderman W. H. Brittain, Mr. E. Howarth (Sheffield); Mr. Joseph Clarke, Mr. G. N. Maynard (Saffron Walden); Mr. J. Storrie (Cardiff); Mr. Butler Wood (Bradford); Mr. C. Madeley (Warrington); Mr. J. Lyon, Mr. J. J. Ogle (Bootle); Mr. W. E. Hoyle (Owens College, Manchester); Mr. H. M. Platnauer (York); Mr. F. W. Rudler, Mr. F. A. Bather, Mr. A. Smith Woodward.

The proceedings were opened by the Rev. H. H. Higgins (Past-President), who introduced the President, Mr. J. Willis Clark. The President then read his address, and gave a short and very interesting account of the early history of Cambridge and of the foundation of a few of the older Colleges. On the 8th and 9th the following papers and reports were read and discussed:—

"On some old Museums," by Prof. A. Newton, F.R.S.

"On the desirability of exhibiting, in Museums, unmounted skins of birds," by the Rev. H. H. Higgins.

"On difficulties incidental to Museum demonstrations," by F. W. Rudler.

"On the Dresden Museum cases," by Dr. A. B. Meyer.

"On the registration and cataloguing of Specimens," by W. E. Hoyle.

"Some recent Museum legislation," by E. Howarth.

"On the arrangement of Rock Collections," by H. M. Platnauer.

"Fossil Crinoidea in the British Museum" (an attempt to put into practice modern ideas of Museum arrangement), by F. A. Bather.

"On Tables and Chairs," by F. A. Bather.

The Report of the Committee appointed to consider the question of securing the aid of specialists.

The Report of the Committee appointed to consider the question of labelling in Museums.

The meeting was eminently pleasant and successful, thanks to the untiring energy and exertions of the President and of Mr. S. F. Harmer (Fellow of King's College), the Local Secretary and Treasurer. Under their guidance several colleges, libraries, and laboratories were visited. Prof. Middleton conducted a party over the Fitzwilliam Museum, and, through the kindness of Prof. Newton, a few of the members visited the Pepysian Library.

TECHNICAL EDUCATION IN INDIA.

SIR AUCKLAND COLVIN, the Governor of the North-Western Provinces of India, has issued an exhaustive minute on technical education in that country, in which the various steps towards the introduction of this system of instruction are summarized. The minute naturally refers chiefly to the North-Western Provinces, but is in fact a summary of what has been done elsewhere. It seems that the idea of introducing technical education in the North-West Provinces, where there has hitherto always been a steadily increasing demand for University education, was first mooted in September 1885, when the attention of the local Government was called to the Madras scheme, which aimed at promoting instruction in industrial arts and manufactures by offering grants-in-aid to encourage the teaching, in schools so aided, of technical science, arts, and handicrafts, and by testing that teaching by a system of public examinations. Nearly a year later the Home Secretary to the Government of India drew up a note on the subject generally, pointing out that there was room for improvement in this branch of education in the great north-west, and inquiring what was being done. The Director of Public Instruction replied that the question of establishing Faculties of Medicine and Engineering was under consideration in the Allahabad University, and also certain preparatory courses of study, while it was proposed to refer the question of agricultural and veterinary schools to the Local Records Department. In January 1888, Colonel Forbes, replying to questions addressed to him regarding instruction in engineering, said he considered that the practical instruction gained by natives in the large railway workshops at Allahabad, Lucknow, and Lahore, and at the Government workshops at Roorkee, was decidedly bearing fruit in the direction of enabling natives to take intelligent and independent control in these branches of technical industry. The railway and Government workshops he considered were the real technical schools so far as this branch of instruction was concerned, and there was no need, therefore, for the Government to establish technical engineering schools. Facilities might be given to selected students at the middle and high schools to go through a four or five years' course at these workshops, but more than that he held was unnecessary. Colonel Brandreth, the Principal of the Thomason College, was unfavourable to any school for technical education for the youthful masses, but would provide special opportunities for exceptional young men, though such opportunities need only be limited in number. "For the higher grades of engineering, I think the ordinary liberal education with a scientific knowledge is most suited, until a man is of an age to know his mind, and elect for the profession, when there should be a strictly technical education for a limited time, two or three years, followed by a careful apprenticeship on works." The late Colonel Ward contended that facilities should be given at the Roorkee College for practical instruction, in addition to the present theoretical course. "If such a technical practical class were formed at Roorkee, students from the schools might be allowed to attend it without going through the College theoretical course." Later on, the Director of Land Records and Agriculture sent in an opinion on the subjects immediately referred to him, and advocated nothing more than the creation of a normal school for survey only, at Cawnpore or Lucknow, suggesting also the establishment of small scholarships for the maintenance of boys in training at the various workshops in the provinces; of an art school at Lucknow; and of agricultural and veterinary schools or classes in high schools; and he proposed that drawing should be made compulsory, competency to teach drawing being prescribed as an essential qualification in all teachers in middle and high class schools. And finally, the Inspector-General of Civil Hospitals reported against the proposal to teach up to a higher standard than that of the hospital assistant class. Then, in March 1888, the Director of Public Instruction forwarded a second report adverse to the establishment of a school of art at Lucknow, and pointing out further that, however desirable was the proposal to introduce drawing into public schools, there were no funds available for the purpose. At the close of the year the Director forwarded a resolution, on the part of the Senate of the Allahabad University, to the effect that any steps to establish a College for training medical practitioners would at present be premature. At this point, says the *Times of India*, in discussing Sir Auckland Colvin's minute, the cold water current ceased. In the February of last year the Director of Public Instruction forwarded a minute by the Allahabad Senate, it which it was decided to establish a Faculty of Engineering, degrees being conferred on men who had passed at least a three years' theoretical course at a properly constituted Engineering College or school. On this subject Sir Auckland Colvin now reports that, so far as he is able to gather, the only place at which engineering can be studied in the North-West Provinces is Roorkee. The Public Works Department, he adds, is of opinion that if degrees are to be conferred by the Allahabad University the Roorkee certificate must be abolished, and the Department prefers Roorkee certificates. In this dilemma the resolution of the Senate has not yet been forwarded to the Government. Then the establishment by the University of a special examination of "a commercial and practical character," aiming apparently at forming a sort of training class for technical education, still remains under consideration. The general conclusion, Sir A. Colvin thinks, is that, on the whole, opinion points to nothing more urgent or pronounced than the expediency of giving greater facilities for obtaining instruction in the subordinate grades of practical engineering, and in the handicraft of the artisan. Sir Auckland Colvin then sums up the subsequent papers on the subject, relating to the offer of the British Indian Association, in July 1887, to establish and maintain, at a cost to the Association of Rs. 500 per month, a school of industry in one of the Wingfield Manzil buildings; the announcement of Munshi Imtiaz Ali of additional individual subscriptions, reaching Rs. 17,440 per annum; to the speeches of Sir Alfred Lyall on the subject; and to the draft rules forwarded by the British Indian Association.

Sir Auckland next devotes himself to a consideration of the systems of technical instruction at work in Bombay and Bengal. From a careful study of the facts and the more or less voluminous papers in which they were originally enshrined, he proceeds to define what is meant by technical education so far as it is applicable to the North-West Provinces. Technical education in Europe he illustrates by Mr. Scott Russell's words: "It is necessary that each individual shall, in his own special profession, trade, or calling, know more thoroughly its fundamental principles, wield more adroitly its special weapons, be able to apply more skilfully its refined artifices, and to achieve more quickly and economically the aim of his life, whether it be commerce, manufactures, public works, agriculture, navigation, or architecture;" and by an extract from Mr. Kirkham's report, in February 1889, to the Bombay Government: "The general principles that the real technical school is the actual workshop—that actual workshops are only called into existence by capital operating in accordance with its own law—that this training, so far as it can be given in schools or colleges, must be, in the main, preparatory and disciplinary, and that the improvement of science teaching all round, and the spread of a practical knowledge of drawing, are the indispensable preliminaries of any form of practical training." But however unanimous the authorities may be so far as the principle of the matter is concerned, directly they come to the practical details there is, as Mr. Kirkham admits, every degree of diversity of opinion, and every system is of course bound in a way to differ from every other system, just as the leading industries of different districts differ. Apart from this, however, the Bombay system was found to be far too elaborate for the North-West Provinces. From Bengal Sir Alfred Croft wrote a very practical and sensible letter, condemning the abolition of the Seebpore workshops, and urging that the primary point, so far as engineer students were concerned, was to learn how to use their hands. He also quoted Mr. Spring, who says there can be no question as to their superiority for public works employment if the men have gone through the course of manual training. "An engineer who has learned to use his hands is, other things being equal, an all-round better and more useful man than one who has not." Sir A. Croft goes on to further condemn the removal of the Seebpore shops from the point of view of the need of the mechanic class. "It may be freely admitted and taken as proved that the maintenance of the shops is undesirable from the point of view of the Public Works Department. But it is no less clear to me that the interests of that Department are in this matter antagonistic to those of technical education; and that the deliberations of the Committee have been chiefly governed by regard to the former." The Government, however, remained in principle unmoved; but happily in practice they agreed with the Director of Public Instruction, and the Government of India followed suit; thus establishing a very important principle in regard to technical education. Armed with all this experience, and conceding for the moment the

Digitized by Google

existence of a demand for men competent to deal with machinery and familiar with all the lower forms of engineering, Sir A. Colvin proceeds to discuss what course the training should take, how best to secure it, and the sources from which the necessary funds could be obtained. With regard to the first point, he thinks that what would mostly be required are facilities for gaining a competent theoretical and practical knowledge of the more subordinate grades of mechanical engineering, such as is necessary to a foreman mechanic, more especially in connection with the steam-engine, the railway workshops, and the iron-foundry; and also of the processes of cotton-spinning as employed in the mills established in the North-West Provinces. "These are the two great branches of industry which in Bombay have been recognized as fields for native labour: which, though in a lesser degree, exist here (in the North-West Provinces), and in regard to which, at present, specialized means of instruction are unquestionably, in these provinces, wanting." With regard to the second point, there exists at Roorkee a Government Engineering College and Government workshops, and it seems probable that these will form the nucleus of the instruction necessary. As to the third point, Sir Auckland Colvin thinks it would be premature to enter into the question of funds until the dimensions of the scheme are definitely decided upon. Finally, to see how far all these views meet the industrial needs of the province, Sir Auckland has decided to seek the aid of a strong Committee, which will obtain from all available quarters information on the points indicated in the minute, deputing members to Calcutta, Bombay, and Madras, and subsequently reporting to Government the result of its inquiries, with its own recommendations, and with full details of any scheme which it may desire to see carried into effect.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The judges for the Johnson Memorial Prize, 1891, have awarded the prize to Mr. M. S. Pembrey, B.A., Christ Church. The judges also select the essays of the following as worthy of mention: Mr. T. I. Pocock, Scholar of Corpus Christi College, and Mr. F. T. Howard, B.A., Balliol College. The Johnson Prize consists of a gold medal of the value of ten guineas, together with the surplus dividends on the money invested. The prize is awarded every fourth year to the candidate who produces the best essay on some subject connected with astronomy or meteorology. The selection of a subject is left to the discretion of the candidates. This year there were six candidates.

Mr. Pembrey was a Fell Exhibitioner of Christ Church, gained a first class in the final honour school of natural science in 1889 (physiology), and obtained the Radcliffe Travelling Fellowship in 1890. Mr. Pocock was placed in the first class of mathematical moderations and also in the final mathematical schools, Trinity term 1891. Mr. Howard was placed in the second class of the final honour school in natural science (geology), and obtained the Burdett-Coutts Scholarship in 1890.

SOCIETIES AND ACADEMIES.

LONDON.

Chemical Society, June 18.—Prof. A. Crum-Brown, F.R.S., President, in the chair.—The following papers were read:—A note on some new reactions of dehydracetic acid, by Dr. J. Norman Collie. In preparing dehydracetic acid, by passing ethyl aceto-acetate through a red-hot tube, it is stated that alcohol is formed; the author finds that large quantities of ethylene gas and acetone are also produced. Dehydracetic acid is also volatile to a considerable extent with steam, and is decomposed by boiling with water to a small extent into carbon dioxide and dimethylpyrone. This latter decomposition is more readily effected by boiling the acid with strong hydrochloric acid. If 50 grams are boiled with ordinary fuming hydrochloric acid, the whole is converted into carbon dioxide and a soluble compound of dimethylpyrone with hydrochloric acid. The barium salt of dehydracetic acid, $(C_8H_9O_5)_2Ba$, seems to be not a salt of the compound $C_8H_8O_4$, but of the true tetracetic acid, $C_8H_{10}O_6$. A very stable copper salt of the formula $C_{24}H_{28}O_9N_2Cu$ is obtained if dehydracetic acid be added to a solution of copper acetate in a large excess of ammonia.—The lactone of triacetic acid, by Dr. J. Norman Collie. In a former paper on the constitution of dehydracetic acid (Trans. Chem. Soc., 1890, 189) the author pointed out that if the formula which he proposed for dehydracetic acid was correct, it would be the δ-lactone of tetracetic acid. And the following list was given showing the connection between the condensed acids formed from acetic acid: $CH_3CO.(CH_2CO)_2.CH_2COOH$, tetracetic acid; $CH_3CO.CH_2CO.CH_2COOH$, triacetic acid; CH_3COCH_2COOH, diacetic acid; CH_3COOH, acetic acid. At that time no acid corresponding to the triacetic acid was known. Since then the author has obtained the lactone of this acid by the action of 90 per cent. sulphuric acid on dehydracetic acid at a temperature of 130°–135°. The properties and reactions of the new compound are described.—The refractive power of certain organic compounds at different temperatures, by Dr. W. H. Perkin, F.R.S. The magnetic relations of substances when examined at temperatures wide apart show that certain variations take place after allowing for change of density. Experiments have been made by the author in reference to the refractive power of liquids under similar circumstances. The results show that the specific refractive power is not constant for all temperatures. By comparing the lines A and F it was found that the dispersion was slightly diminished by rise of temperature. The results were calculated by the formula $\frac{\mu - 1}{d}$. When calculated by Lorentz's formula the numbers gave higher results for high temperatures than for lower ones.—Note on a volatile compound of iron and carbonic oxide, by Ludwig Mond, F.R.S., and Dr. F. Quincke (see NATURE, July 9, p. 234).—The formation of salts, a contribution to the theory of electrolysis and of the nature of chemical change in the case of non-electrolytes, by H. E. Armstrong. The author draws attention to the recent researches of Claisen, W. Wislicenus, and others, which clearly show that ethereal salts form compounds with sodium ethylate, and to the bearing which these results have on the theory of the formation of salts generally. It may be supposed that the acid and the "base" in the first instance combine, and that the salt is formed by subsequent interactions within the molecule. In like manner, acids form dissociable compounds with water, and by the occurrence of change within such systems, under the influence of electromotive force, electrolysis is effected. When the compound is highly unstable, the opportunity for change within its system is slight, the acid is a weak one, and its solution of relatively low conducting power. In the case of non-electrolytes, the occurrence of change may be supposed to occur within complex systems formed by the union of the interacting substances.—Dibenzyl ketone, by Dr. S. Young. The author finds that, in preparing the ketone by heating calcium phenyl acetate in a combustion furnace, only 27 per cent. of the theoretical yield is obtained. However, if the calcium salt be heated by means of the vapour of boiling sulphur, the yield of pure ketone amounts to 76·6 per cent.—The vapour-pressures of dibenzyl ketone, by Dr. S. Young.—The vapour-pressures of mercury, by Dr. S. Young. Two additional observations of the vapour-pressures of mercury at 183°·75 and 236°·9 have been made, and, from the previous results of Ramsay and Young, the boiling-point and the vapour-pressures of mercury have been recalculated.

June 25.—Extraordinary General Meeting.—At the request of certain Fellows to the President, an extraordinary general meeting was summoned to consider a proposal for amending and altering the by-laws. The proposal was moved by Mr. James Wilson and seconded by Dr. Teed. Mr. Cartrighe moved the following amendment: "That this meeting declines to pledge itself to any amendment or modification of the by-laws which has not been approved and recommended to the Fellows for adoption by the Council." Sir F. A. Abel seconded the amendment. Mr. Cassell, Mr. Lloyd, and Dr. Newton spoke in favour of the original motion. Prof. Tilden, Mr. Warington, Mr. Page, Dr. Odling, and Mr. Friswell spoke in favour of the amendment. The amendment was carried by 137 votes to 47 votes.

PARIS.

Academy of Sciences, July 13.—M. Duchartre in the chair.—Calculation of the mean length that a circular tube widened at one end should have in order that a sensibly uniform *régime* might be established, and on the expenditure of the charge that entails the establishment of this *régime*, by M. J. Boussinesq.—Contribution to the study of what are called *natural* prairies, by M.

A. Chatin.—On alkyl cyanides, cyanobenzene, and orthocyanotoluene, by M. A. Haller.—Experimental aërodynamic researches and experimental data, by Prof. S. P. Langley (see p. 277).—Observations of solar spots and faculæ, made with the Brunner equatorial of Lyons Observatory, during the first six months of this year, by M. Em. Marchand.—On a modification of the method of supporting railway and tramway vehicles, by M. Féraud.—On the measurement of capacity, self-induction, and mutual induction by experiments on aërial wires, by M. Massin.—On a new copper hydride and the preparation of pure nitrogen, by M. A. Leduc. The new body was discovered in the course of some experiments on the preparation of pure nitrogen by passing undried air deprived of CO_2 over copper turnings in a glass tube heated to redness and then reducing the resulting oxide by hydrogen. The composition and properties of this hydride have not yet been studied, but from the fact that it is formed at red heat it appears to differ from the body discovered by Wurtz, which is broken up at about 60° C.—Action of light on silver chloride, by M. Guntz. The experiments indicate that when a layer of silver chloride is exposed to light it becomes divided into three superficial layers, the first of which is metallic silver; the second silver subchloride; and the third unaltered silver chloride. These three layers have a thickness which is a function of the duration of exposure, and of the primitive thickness of the layer of silver chloride experimented upon.—On a new gaseous compound, phosphorus pentafluochloride, by M. C. Poulenc. The formation of this compound is expressed by the formula $PF_3 + Cl_2 = PF_3Cl_2$, which also indicates that a contraction of volume occurs. This has been proved experimentally. The gas is colourless, and has an irritating odour. Its density is 5·40, and it may be liquefied at ordinary pressures by reduction to a temperature of − 8°. Reactions with sulphur, phosphorus, sodium, magnesium, mercury, and various other substances, are described. It appears to be a much less stable body than Prof. Thorpe's phosphorus pentafluoride.—Compound of boron bromide with phosphoretted hydrogen; phosphide of boron, by M. A. Besson. Bromide of boron absorbs phosphoretted hydrogen at ordinary temperatures, and the result of the combination is a white, amorphous, very light solid. The composition of this product appears to be represented by the formula BBr_3PH_3. At about 300° it changes colour, and hydrobromic acid is disengaged. The dark brown body that remains is found to contain only phosphorus and boron, the action that takes place being expressed thus—$BBr_3PH_3 = PB + 3HBr$. Boron phosphide has a density about the same as water, in which it is insoluble. Reactions with various substances have been investigated.—Researches on the zirconates of the alkaline earths, by M. L. Ouvrard. One interesting point brought out by the experiments is that an analogy exists between zirconium, tin, and titanium.—Artificial production of datolite, by M. A. de Gramont. By the action of a solution of borate of sodium on silicate of calcium (formed by the precipitation of calcium chloride by sodium silicate) at a high temperature and under pressure, a hydrated silico-borate of calcium has been obtained, which in composition and physical properties appears to be identical with datolite. This is the first silico-borate of definite composition, and corresponding to a natural product, which has yet been obtained.—Action of boron fluoride on nitriles, by M. G. Patein.—On the acid sulphate waters containing iron and aluminium of the environs of Rennes-les-Bains (Aude), by M. Ed. Willm.—On the formation and oxidation of nitrites during nitrification, by M. S. Winogradski.—On the larva form of Parmophori, by M. Louis Boutan.—On the circulatory and respiratory apparatus of some Arthropods, by M. A. Schneider.—On the genus *Euclea* (Ebenaceæ), by M. Paul Parmentier.—On the structure of the primary libero-ligneous system, and on the disposition of foliary traces in the branches of *Lepidodendron selaginoides*, by M. Maurice Hovelacque.—On a fall of small calcareous stones which recently occurred in the Department of the Aude, by M. Stanislas Meunier.

AMSTERDAM.

Royal Academy of Sciences, June 27.—Prof. van de Sande Bakhuyzen in the chair.—Mr. Pekelharing communicated that magnesium-sulphate-plasma or kalium-oxalate-plasma contains a substance which has no active power on pure fibrinogen, but acquires by a combination with lime-salts all the properties of fibrin ferment prepared from washed blood-clot. This substance is precipitated incompletely by dialysis, and completely by saturation with magnesium-sulphate. Its combination with lime is active also in the presence of ammonium-oxalate. In the formation of fibrin, lime is transferred from the ferment to the fibrinogen. Pepton prepared by neutralizing the hydrochloric acid of the digesting fluid with calcium-carbonate, injected in the jugular vein of the dog, does not prevent the clotting of the blood. Wooldridge's "tissue-fibrinogen," prepared from the thymus of the calf, causes coagulation of a pure solution of Hammarsten's fibrinogen when lime-salts are present.—Mr. van Bemmelen communicated a research of Mr. Schreinemaker's on the equilibriums which are possible between the double salt $PbI_2 2KI$ and water, in the presence or the absence of an excess of one of the components, or of the double-salt itself, or of both. The results are in accordance with the investigations of Dr. Bakhuis Rooseboom.—Mr. Suringar presented to the Academy a new (third) contribution to our knowledge of the Melocacti of the West Indies.

MESSRS. MACMILLAN & CO.'S PUBLICATIONS.

BY SIR ARCHIBALD GEIKIE, LL.D., F.R.S.

New and Revised Edition. Globe 8vo, 3s. 6d.

OUTLINES OF FIELD GEOLOGY. By Sir ARCHIBALD GEIKIE, LL.D., F.R.S., Director-General of the Geological Survey of Great Britain and Ireland.

"This volume has now been thoroughly revised and considerably enlarged. One of the chief changes will be found in the account of the schistose rocks, which has been re-written in the light of recent researches into these interesting but difficult parts of the geological record. A number of new illustrations have been added from my note-books."—From the Author's Preface.

BIRMINGHAM DAILY GAZETTE:—"In truth the book is as complete as care and experience can make it, and to every geological student its value is inestimable."

SCOTSMAN:—"Prof. Geikie condenses for the advantage of the student the results of many years' practice and experience in actual geological research. The utility of the book is enhanced by numerous diagrams and woodcuts."

GLASGOW HERALD:—"We can still more heartily recommend this book to all who wish to gain a practical knowledge of geological work in quarry or cutting, on mountain, in glen, or open country. The woodcuts are beautiful, and illustrate the text admirably."

HARDWICKE'S SCIENCE GOSSIP:—"A small volume ably and clearly written, and which cannot fail to take its place as one of the best introductions to the study of geology."

NORTH BRITISH DAILY MAIL:—"This clever little volume will be highly appreciated. Prof. Geikie has supplied what has long been felt to be a great want. The numerous illustrations and diagrams will be found to be of the very greatest assistance to the practical student."

NEW EDITION OF SIR J. W. DAWSON'S ACADIAN GEOLOGY.

Just Published, Fourth Edition, Royal 8vo, Cloth, 21s

THE GEOLOGY OF NOVA SCOTIA, NEW BRUNSWICK, AND PRINCE EDWARD ISLAND, or ACADIAN GEOLOGY. By Sir J. WILLIAM DAWSON, LL.D., F.R.S., F.G.S., Principal and Vice-Chancellor of McGill College and University, Montreal. Fourth Edition, with Map, Illustrations, and 2 Supplements.

NEW AND REVISED EDITION OF AIRY'S POPULAR ASTRONOMY.

Just Published, Seventh Edition, Fcap. 8vo, 4s. 6d.

POPULAR ASTRONOMY: a Series of Lectures delivered at Ipswich by Sir GEORGE BIDDELL AIRY, K.C.B., late Astronomer-Royal. Revised by H. H. TURNER, M.A., B.Sc., Chief Assistant, Royal Observatory, Greenwich.

This edition has been very carefully revised by the Chief Assistant of the Royal Observatory, Greenwich, who has, however, introduced no more changes than were absolutely necessary to bring so well-established a book up to date.

BOOKS FOR CHEMICAL STUDENTS.

AUTHORIZED ENGLISH TRANSLATION OF MEYER'S HISTORY OF CHEMISTRY.

8vo, Cloth, 14s. net.

A HISTORY OF CHEMISTRY FROM THE EARLIEST TIMES TO THE PRESENT DAY. Being also an Introduction to the Study of the Science. By ERNST VON MEYER, Ph.D., Professor of Chemistry in the University of Leipzig. Translated with the Author's sanction by GEORGE MCGOWAN, Ph.D., Demonstrator in Chemistry, University College, North Wales, Bangor.

SPEAKER:—"A standard book on the subject. The conclusions are obviously the outcome of wide knowledge, independent research, and sound judgment."

SCOTSMAN:—"The book is an admirable one in every way. Beginning with the origin of chemistry as found in alchemy, it traces the history of the science down to the present time. The author gives a clear account of the genesis of chemical theory, and at the same time presents a comprehensive history of the progress of knowledge of the various departments. The account of the development of the atomic theory is particularly well done."

NEW AND THOROUGHLY REVISED EDITION.

8vo, Cloth, 18s.

A COMPLETE TREATISE on INORGANIC AND ORGANIC CHEMISTRY. By Sir HENRY E. ROSCOE, F.R.S., and Prof. C. SCHORLEMMER, F.R.S.

Vol. III.—THE CHEMISTRY OF THE HYDROCARBONS, and their Derivatives, or ORGANIC CHEMISTRY. Six Parts. Part III. New and Thoroughly Revised Edition.

CHEMICAL NEWS:—"As a systematic treatise on chemistry the work in its entirety has no equal in the English language."

ACADEMY:—"The authors are evidently bent on making their book the finest treatise on systematic chemistry in the language."

IRON:—"One of the best treatises in our language."

Globe 8vo, 6s.

MIXED METALS OR METALLIC ALLOYS. By ARTHUR H. HIORNS, Principal of the School of Metallurgy, Birmingham and Midland Institute.

CHEMICAL NEWS:—"The best manual of alloys to be met with in the English language."

BY THE SAME AUTHOR.

PRACTICAL METALLURGY AND ASSAYING. A Text-book for the use of Teachers, Students, and Assayers. With Illustrations, Globe 8vo, 6s.

A TEXT-BOOK OF ELEMENTARY METALLURGY. For the use of Students. Globe 8vo, 4s.

IRON AND STEEL MANUFACTURE. A Text-book for Beginners. Illustrated. Globe 8vo, 3s. 6d.

THE RIGHT HAND: LEFT HANDEDNESS. By Sir DANIEL WILSON, LL.D., F.R.S.E., President of the University of Toronto.

Just ready, 8vo, Cloth, 12*s.* net.

THE POSITIVE THEORY OF CAPITAL. By EUGEN V. BÖHM-BAWERK, Counsellor in the Austrian Ministry of Finance, and Honorary Professor of Political Economy in the University of Vienna. Translated, with a Preface and Analysis, by WILLIAM SMART, M.A., Lecturer on Political Economy in Queen Margaret College, Glasgow.

BY THE SAME AUTHOR AND TRANSLATOR.

8vo. Price reduced to 12*s.* net.

CAPITAL AND INTEREST: a Critical History of Economical Theory. By EUGEN V. BÖHM-BAWERK, Honorary Professor of Political Economy in the University of Vienna. Translated, with a Preface and Analysis, by WILLIAM SMART, M.A., Lecturer on Political Economy in Queen Margaret College, Glasgow.

WITH PREFACE BY DR. A. R. WALLACE.

8vo, Cloth, 14*s.* net.

THE HISTORY OF HUMAN MARRIAGE. By EDWARD WESTERMARCK, Ph.D., Lecturer on Sociology at the University of Helsingfors.

I have seldom read a more thorough or a more philosophic discussion of some of the most difficult, and at the same time interesting, problems of anthropology. . . . On some points Mr. Westermarck has arrived at different and sometimes diametrically opposite conclusions from those of Darwin, Spencer, Morgan, Tylor, Lubbock, and he has done so after a most complete and painstaking investigation of all the available facts.

With such an array of authority on the one side and a hitherto unknown student on the other, it will certainly be thought that all the probabilities are against the latter. Yet I venture to anticipate that the verdict of independent thinkers will, on most of these disputed points, be in favour of the new comer who has so boldly challenged the conclusions of some of our most esteemed writers. Even those whose views are here opposed will, I think, acknowledge that Mr. Westermarck is a careful investigator and an acute reasoner, and that his arguments, as well as his conclusions, are worthy of the most careful consideration.

Every reader of the work will admire its clearness of style and the wonderful command of what is to the author a foreign language.—From Dr. WALLACE'S Preface.

TIMES:—"Very learned and elaborate, scientifically conceived and scientifically executed. It should command the serious attention of all scientific students of sociology."

NEW VOLUMES OF MACMILLAN'S MANUALS FOR STUDENTS.

A NEW TEXT-BOOK OF CRYSTALLOGRAPHY.

Crown 8vo, Cloth, 6*s.*

ELEMENTS OF CRYSTALLOGRAPHY FOR STUDENTS OF CHEMISTRY, PHYSICS, AND MINERALOGY. By GEORGE HUNTINGDON WILLIAMS, Ph.D., Assistant Professor in the Johns Hopkins University.

*** A concise and elementary statement of the general principles of Crystallography, not intended as a complete treatise, but to furnish so much information on the subject as may be of service to students of other but allied branches.*

NATURE:—"We feel assured that the simultaneous publication in this country and in America of so simple and at the same time so accurate a text-book of the subject as the work we are now considering will do much towards reviving and diffusing a taste for the study of crystallography. The student who masters the contents of this little book will undoubtedly have much more to learn before he is competent to deal with all the higher problems of crystallographic science; but, however far his researches may be carried in the future—and this is, perhaps, the very highest praise we can give to the book—he will certainly have little, if anything, to *unlearn*."

Crown 8vo, Cloth, 10*s.* 6*d.*

LESSONS IN ELEMENTARY BIOLOGY. By T. JEFFREY PARKER, B.Sc., F.R.S., Professor of Biology in the University of Otago, Dunedin, New Zealand. Illustrated.

NEW EDITION, REVISED.

Crown 8vo, Cloth, 10*s.* 6*d.*

A COURSE OF PRACTICAL INSTRUCTION IN BOTANY. By F. O. BOWER, D.Sc., F.R.S., Regius Professor of Botany, Glasgow.

NATURE:—"Everyone perusing the volume must be impressed with the high standard of its educational value. Teacher and student in this country are alike to be congratulated upon its publication."

ACADEMY:—"The work is one which should be in the hands of every practical botanist."

SATURDAY REVIEW:—"The types are good, easily obtained, and thoroughly worked out. . . . There is no padding, the text is to the point, and it assumes the presence of the plant concerned and the instruments in hand. We regard the absence of illustrations and of descriptive padding as important preventives of cram, and it should be clearly borne in mind that laboratory teaching suffers especially by the opening up of royal roads."

MACMILLAN AND CO., LONDON.

SIMPLE BUT EFFECTIVE.

McLEOD'S SUNSHINE RECORDER.

This ingenious instrument, which is the invention of Prof. McLeod, F.R.S., of Cooper's Hill College, Staines, consists of a cylindrical metallic camera, opposite to the lens of which is a thin glass sphere silvered inside. The sphere is mounted on a slide provided with rack and pinion for focussing the image of the sun on the sensitised paper placed in the base. The instrument must be placed with its vertical plane in the meridian and inclined with the sphere upwards so that the axis of the camera makes an angle with the horizontal equal to the latitude of the place at which it is set up. The support is constructed to suit the latitude; the observer has merely to place the instrument in the meridian.

THE NEW PATENT WATKIN ANEROID BAROMETER.

PRICE FROM £5 to £7. ALSO MADE WATCH SIZE.

Amongst many unsolicited Testimonials the following has been received by the maker:—

EDINBURGH, May 31, 1889.

DEAR SIR,—I have just returned from a six weeks' stay at the Ben Nevis Observatory, and while there had an opportunity of testing the admirable qualities of your new "Watkin" Aneroid. The result has been most satisfactory, the extreme error noted being only about $\frac{1}{10}$th of an inch. During my stay at the Observatory the Aneroid was frequently tested by taking it down 2000 feet and then comparing it with the standard on my return. The results obtained speak volumes for the high-class workmanship and great accuracy you have attained in the manufacture of this instrument.

(Signed) R. C. MOSSMAN, F.R.M.S., Observer, Scott. Met. Soc.

To be obtained of all Opticians and Wholesale Houses.

SIMPLE BUT EFFECTIVE.

McLEOD'S SUNSHINE RECORDER.

This ingenious instrument, which is the invention of Prof. McLeod, F.R.S., of Cooper's Hill College, Staines, consists of a cylindrical metallic camera, opposite to the lens of which is a thin glass sphere silvered inside. The sphere is mounted on a slide provided with rack and pinion for focussing the image of the sun on the sensitised paper placed in the base. The instrument must be placed with its vertical plane in the meridian and inclined with the sphere upwards so that the axis of the camera makes an angle with the horizontal equal to the latitude of the place at which it is set up. The support is constructed to suit the latitude; the observer has merely to place the instrument in the meridian.

PRICE £6 15s.

UNIVERSITY COLLEGE, LONDON.

The Session of the Faculty of Medicine will commence on OCTOBER 1. Introductory Lecture at 4 p.m., by Prof. VICTOR HORSLEY, M.B., B.S., F.R.S., Assistant Surgeon to University College Hospital.

The Examinations for the Entrance Exhibitions will commence on SEPTEMBER 23.

Scholarships, Exhibitions, and Prizes of the value of £800 are awarded annually.

In University College Hospital about 3000 In-patients and 35,000 Out-patients are treated during the year. Thirty-six appointments, eighteen being resident, as House Surgeon, House Physician, Obstetric Assistant, &c., are filled up by competition during the year, and these, as well as all Clerkships and Dresserships, are open to Students of the Hospital without extra fee.

Prospectuses, with full information as to Classes, Prizes, &c., may be obtained from the College, Gower Street, W.C.

E. A. SCHÄFER, F.R.S., Dean.
J. M. HORSBURGH, M.A., Secretary.

BALLIOL COLLEGE, CHRIST CHURCH, AND TRINITY COLLEGE, OXFORD.

NATURAL SCIENCE SCHOLARSHIPS AND EXHIBITIONS.

A combined Examination for Natural Science Scholarships and Exhibitions will be held by the above Colleges, beginning on TUESDAY, NOVEMBER 17, 1891.

Three Scholarships and Two Exhibitions will be offered, the Scholarships being worth £80 a year.

The subjects for examination will be Physics, Chemistry, and Biology, but Candidates will not be expected to offer themselves in more than two of these.

Particulars may be obtained by application to A. VERNON HARCOURT, Christ Church, Oxford.

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR.

(Incorporated under Royal Charter. Departments: Arts, Science, Agriculture.)

AGRICULTURAL DEPARTMENT.

A complete Course of Instruction in Agriculture and Dairying has now been organized.

Full information about College Classes, Scholarships, Diplomas in Agriculture, Certificates in Dairying, &c., will be found in the Agricultural Prospectus (free on application).

The average cost of living in Bangor, including College fees, is about £40 for the College year.

The Next Session begins on SEPTEMBER 29, 1891.

W. CADWALADR DAVIES, Secretary and Registrar.

HARTLEY INSTITUTION, SOUTHAMPTON.

Wanted, a DEMONSTRATOR and TEACHER of PHYSICAL SCIENCE and CHEMISTRY, highly qualified in Physics, and of experience in the management of classes. Salary, £100 per annum and one-third of the Government Grants. Full particulars may be obtained.

Applications for the Appointment must be received by the SECRETARY on or before THURSDAY, AUGUST 13, 1891.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF.

The CHAIR of GREEK is now Vacant through the Resignation of Prof. ROBERTS. The Council will proceed to the Appointment of the new Professor in September Next. The Stipend of the Professor will be £350 per Annum.

Applications, together with Testimonials and References, should be forwarded before TUESDAY, SEPTEMBER 8, 1891.

For further Information apply to

IVOR JAMES, Registrar.

Cardiff, August 4, 1891.

WANTED IMMEDIATELY, a HEAD

MASTER for the proposed TECHNICAL DAY SCHOOL, which will be conducted as an Organized Science School, in connection with the Science and Art Institute, Walsall.

Accommodation will be provided for about 75 Boys. Candidates will be required to give the whole of their time to the work, and must have had experience as Practical Teachers, holding qualifications in Mathematics, Drawing (D), and the usual Science Subjects.

Salary, £170 per Year, guaranteed; with probable Share of Grant earned from Science and Art Department after the first year.

Applications, giving Full Particulars of Qualifications, stating Age, &c., and inclosing Copies of Three Recent Testimonials, to be addressed to the undersigned, on or before AUGUST 12, 1891.

CHARLES CAMWELL, Secretary.

Science and Art Institute, Walsall, July 27, 1891.

LIVING SPECIMENS FOR THE MICROSCOPE.

Gonium pectorale, Volvox globator, Melicerta ringens, Plumatella repens, Paludicella Ehrenbergi, and other beautiful specimens of Pond-life, 1s. per Tube, with Drawing and Description. Amœba, &c., for Students of Biology.

List Post Free.

THOMAS E. BOLTON,
FARLEY ROAD, MALVERN LINK.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL,

ALBERT EMBANKMENT, LONDON, S.E.

The WINTER SESSION of 1891-92 will open on THURSDAY, OCTOBER 1, when the Prizes will be distributed at 3 p.m. by Sir G. M. HUMPHRY, M.D., LL.D., F.R.S.

TWO ENTRANCE SCIENCE SCHOLARSHIPS of 125 guineas and £60 respectively, open to all first-year Students, will be offered for competition. The Examination will be held on September 26, 28, and 29, and the subjects will be Chemistry and Physics, with either Physiology, Botany, or Zoology, at the option of Candidates.

Scholarships and Money Prizes of considerable value are awarded at the Sessional Examinations, as also several Medals.

Special Classes are held throughout the year for the Preliminary Scientific and Intermediate M.B. Examinations of the University of London.

All Hospital Appointments are open to Students without charge.

The Fees may be paid in one sum or by instalments. Entries may be made separately to Lectures or to Hospital Practice, and special arrangements are made for Students entering in their second or subsequent years; also for Dental Students and for Qualified Practitioners.

A Register of approved Lodgings is kept by the Medical Secretary, who also has a List of local Medical Practitioners, Clergymen, and others who receive Students into their houses.

Prospectuses and all particulars may be obtained from the Medical Secretary, Mr. GEORGE RENDLE.

G. H. MAKINS, Dean.

GUY'S HOSPITAL MEDICAL SCHOOL.

The WINTER SESSION begins on THURSDAY, OCTOBER 1.

The Hospital contains 695 Beds, of which 500 are in constant occupation. Special Classes are held for the M.B. Camb. and Lond., the F.R.C.S. Eng., and other and Higher Examinations.

APPOINTMENTS. — All Hospital Appointments are made in accordance with the merits of the Candidates, and without extra payment.

ENTRANCE SCHOLARSHIPS in September 1891.—Two Open Scholarships in Arts, one of the Value of 100 Guineas, open to Candidates under 20 Years of Age; and one of 50 Guineas, open to Candidates under 25 Years of Age. Two Open Scholarships in Science, one of the Value of 125 Guineas, and another of 50 Guineas, open to Candidates under 25 Years of Age.

PRIZES are awarded to Students in their various years, amounting in the aggregate to more than £450.

DENTAL SCHOOL.—A Dental School attached to the Hospital affords to Students all the instruction required for a Licence in Dental Surgery.

COLLEGE.—The Residential College accommodates about Fifty Students in addition to the Resident Staff of the Hospital. There is in it a large Dining Hall, with Reading Rooms, Library, and Gymnasium for the use of the STUDENTS' CLUB.

For Prospectus and further information apply to the Dean, Dr. PERRY, Guy's Hospital, London, S.E.

THE AGRICULTURAL COLLEGE, ASPATRIA.

PRINCIPAL—DR. H. J. WEBB, B.Sc.

Thorough practical and scientific Training in Agriculture. Preparation for the Colonies. Students gained the First, Third, and Fourth Scholarships of the Royal Agricultural Society, 1888; First in Agriculture Junior Scholarships, 1889; First in Agriculture Senior Scholarships, 1890.

CEYLON, JAVA, BORNEO, AND NEW GUINEA INSECTS, especially Lepidoptera and Coleoptera, single or in lots. Also Orthoptera and Dragon flies, LAND AND FRESH-WATER SHELLS, offered at cheap prices.—H. FRUHSTORFER, Naturalist, care of German Consulate, Soerabaia, Java.

SYNOPSIS DER HOEHEREN MATHEMATIK.

VON JOHANN G. HAGEN, S.J.,

Director der Sternwarte des Georgetown College, Washington, D.C.

The work is intended to present a general view of the higher mathematics. It may be regarded as exhibiting, like a terrestrial or a celestial chart, a network of co-ordinates, which show at a glance the discoveries made in mathematics up to the present day.

The work is not intended to serve as a text-book; nor is it a mere collection of formulas or tables. It is a book of reference, a kind of "Encyclopædia of the Higher Mathematics," in which the collected material is systematically arranged. While it sets the leading propositions prominently forward, the Synopsis merely indicates the deductions. It is a feature of the Synopsis, entitling it to more than ordinary interest, that it takes notice here and there of the desiderata in the science of mathematics, indicating the points upon which the labour of future investigators may be most profitably employed.

The author has personally examined the whole literature of the science, including not only the works of all the great masters since the time of Euler, but also the articles in periodicals to which he makes reference. He has allowed no quotation to pass without verification, and, wherever found necessary, corrections have been made

The Work will be completed in 4 Volumes. Volume I. will be ready in August, Price 30s., and will contain—

Part I. : Theory of Numbers.—Part II. : Theory of Complex Quantities.—Part III. : Theory of Combinations.

Part IV. : Theory of Series.—Part V. : Theory of Infinite Products and Factorials.—Part VI. : Theory of Continued Fractions.—Part VII. : Theory of Finite Differences.

Part VIII. : Theory of Functions.—Part IX. : Theory of Determinants.—Part X. : Theory of Invariants.—Part XI. : Theory of Groups.

Part XII. : Theory of Equations.

THURSDAY, AUGUST 6, 1891.

A PHYSICIST ON COLOUR-VISION.

Colour-Measurement and Mixture. By Captain Abney. (London: The Society for the Promotion of Christian Knowledge, 1891).

THIS interesting little book extends over only 200 pages, but is full of careful and important observations. It is, in fact, a summary of the results arrived at by the author during his careful and laborious investigation of the properties of the spectrum. It forms one of the "Romance of Science" series published by the S.P.C.K., a series intended "to show that science has for the masses as great an interest as, and more edification than, the romances of the day." Now, though the earlier portion of this book could be understood by anyone, we venture to think that the second half is for the most part so technical that the full meaning and value could only be appreciated by those who are more or less conversant with the methods of experimenting on colour. To those who are familiar to even a slight extent with the technicalities of colour experiments, the characteristic of the book is its extreme lucidity. We are carried on from point to point, until, when we look back on the closed book, we find we have travelled over the greater number of the problems of colour-vision almost without effort. It is a book which will not appeal to the masses, but should be read by every physiologist and physicist interested in colour-vision.

There is yet another reason for the interest which attaches to this work, necessitating a fuller notice than if it were simply a popular disquisition on colour. It is the record of a careful series of experiments by an eminent physicist, firmly convinced of the truth of the Young-Helmholtz theory of colour-vision. The voluminous work of Hering and his pupils is not once mentioned throughout the whole book, although König's later publications receive due notice. In fact, if space permitted, we cannot imagine a book more calculated to form the basis of a fruitful discussion on the merits of the rival theories than that now before us. For both the problems of colour-vision, and their solution according to the Young-Helmholtz theory, are definitely and clearly stated.

The book opens with a description of the methods used to obtain a spectrum, and a consideration of its properties with especial reference to the ultra-red and ultra-violet rays. The apparatus used by the author to investigate the three fundamental properties of colour—hue, luminosity, and purity—are described in detail. Absorption and interference are then touched upon in their relation to colour, and experiments are given to show that the colour of a body is due to its refusal to transmit or reflect certain rays of the spectrum. This is followed by an interesting chapter on scattered light, with especial reference to atmospheric effects, and a pretty lecture-room experiment is described to show that the change in the colour of the sun when on the horizon is produced by small particles in the air.

The author then passes on to consider the second property of colour—luminosity; and the luminosity of the spectral colours is measured as follows. The light from a certain portion of the spectrum passes through a slit which cuts off the remainder of the spectrum. A portion of the same white beam which was decomposed by the prisms is reflected on to the same screen as the monochromatic beam, and an upright rod is interposed. This rod throws two shadows, whose intensity is compared after the manner of a photometer. The luminosity of the whole reflected beam is greater than that of the coloured beam, and a rotating diaphragm, with variable sectors, is therefore interposed in its course. By altering the size of the sectors, the intensity of the white light is diminished, until the luminosity of the shadow it casts is equal to that cast by the monochromatic beam. The luminosity is then read off in terms of the segment of the circular diaphragm which remains open when the luminosity of the two shadows is equalized. The luminosity of all the principal points in the spectrum is measured on this plan. Subsequently the luminosity of a combination of red and green is shown to be equal to the sum of the luminosities of the same red and green determined separately. Three colours, A, B, and C, are chosen, which, when combined, make white of a certain intensity, W; and the author shows that if the luminosity of the combined light A + B be subtracted from the luminosity of the white light, W, the remainder exactly equals the luminosity of the third factor, C.

A curve of luminosity can be constructed in this manner for the whole spectrum, and its maximum is found to lie on the yellow side of the D line. A similar luminosity curve is given for an observer who was what is ordinarily called red-blind. On this curve the red end of the spectrum is shortened, and the maximum luminosity falls nearer the green than on the curve constructed for a person with normal colour-vision. These facts are explained as follows. To the red-blind observer red is invisible, and therefore the luminosity of red is abolished; the luminosity of yellow, which is composed of red and green, is also diminished, and thus the maximum of the curve moves towards the green.

This question of luminosity is intimately associated with the theory of the value of white in the system of colour. The author discusses later on in the book the abolition of colour by white light, and examines the extent to which white light can be added to a colour without being perceived. He finds that both depend on the luminosity of the colour, and formulates the law that "the extinction of every colour is effected by white light that is 75 times brighter than the colour." Again, he finds that a large proportion of white light can be mixed with yellow without being perceived, whilst a very small proportion of white added to blue is at once apparent.

An attempt is made to explain these facts on the Young-Helmholtz theory; but the work done by Hillebrand,[1] under Hering's guidance, makes the explanation offered very improbable. Hillebrand used an apparatus in which one half of the field could be illuminated by a monochromatic spectral colour, whilst the other half was illuminated by white light. The observer shielded one eye from the light for a considerable time, so that it was ultimately brought into a condition of complete rest. Now if he looked at a field filled with monochromatic

[1] "Ueber die specifische Helligkeit der Farben," *Sitzb. d. k. Akad. d. Wissenschaft. in Wien*, February 1889.

Digitized by Google

light of moderate intensity with the rested eye, it appeared to him colourless; and by suitable adjustment he could make an absolute match between the half of the field illuminated by monochromatic light and the other half illuminated by white light from the same source. Thus, as the whole spectrum appeared colourless, he was able to construct a curve of luminosity for the spectrum by matching it with the white light in the other half of the field. The maximum of this curve lay in the green. A glance with the unshaded eye at once brought the colour into view, although the field was unaltered. But as soon as the colour came into view, he noticed that the luminosity of the coloured half no longer matched that of the colourless half of the field. If yellow or red were the colour chosen, the luminosity of the coloured half of the field appeared to exceed that of the colourless half, whilst if green or blue were selected the exact opposite was observed. Moreover, as soon as the colours of the spectrum were appreciated, the maximum luminosity shifted into the yellow, and the curve he then obtained closely resembled that constructed by Captain Abney and other observers. Thus we must conclude that every part of the spectrum is capable of exciting the sensation of white apart from its specific colour, and that the maximum sensation is produced by a certain point in the green. As soon, however, as the colour becomes apparent, this sensation of white is either increased or decreased by the specific luminosity of the colour. The luminosity of the spectrum, as determined by Captain Abney, is the algebraic sum of two factors. Firstly, the power which every part of the spectrum possesses of exciting the sensation of white; and secondly, the specific luminosity of the colour sensation itself, which is a positive quantity on the red and yellow side and a negative quantity in the blue and green.

If this explanation for the difference in the two curves be correct, a person who was completely deficient in colour-sense would construct a luminosity curve for the spectrum differing considerably in the position of its maximum from that given by Captain Abney in his book. The curve obtained by König[1] from a man to whom yellow, blue, green, and red were invisible, to whom the whole spectrum appeared in varying shades of white, shows that this is the case. The maximum luminosity lies in the green, over the line *b*. A comparison of this curve with that given by Hillebrand for the normal eye at rest reveals their almost absolute identity. The existence of this form of colour-blindness can only be explained with extreme difficulty on the Young-Helmholtz theory; whereas Hering's hypothesis, that white and black form a colour pair analogous to red and green, yellow and blue, not only renders the existence of such a condition probable, but also easily explains Hillebrand's results.

The author passes on to show that white can be produced from the mixture of three spectral colours, and ultimately defines a primary colour as one which cannot be formed by the mixture of any other colours. The three primary colours he selects are red, green, and violet; for yellow is formed by a mixture of red and green, blue by a mixture of green and violet. But he warns us from assuming that the three primary colour sensations "are of necessity the same sensations as are given by the three primary colours" (p. 138). On p. 139 red (between C and the lithium line), violet (close to G) are selected as furnishing two primary sensations, whilst "all three fundamental sensations" are excited by the green, except at a point where the green is mixed only with white only.

Now, to say that spectral green excites the sensations of red and violet seems to us radically false. For when speaking of sensations we leave the realm of physics, and the sole test of the sensations excited by a portion of the spectrum is the colour which we perceive when light from that part impinges on the retina. No one who examines spectral green will say that it gives him the sensation of red or violet, but rather that the greater part of spectral green appears to be mixed with either yellow or blue. Again, a primary sensation must be one which gives rise to the sensation of one colour only. Now every eye sees in violet both blue and red. Thus, whether violet be a primary colour from the physical point of view, physiologically speaking it is anything but a primary sensation.

Though violet fails to answer the test of a primary colour sensation, a point can be found both in the yellow and the blue of the spectrum, from which the sensation of one colour only is obtained. But throughout the book we find repeated mention of the formation of yellow by the mixture of spectral red and spectral green. How can this be reconciled with the acceptance of yellow as a primary sensation?

To most eyes, the red of the spectrum yields to a greater or less extent the secondary sensation of yellow. Take such a red, and gradually add minute quantities of spectral blue. The yellow will gradually disappear, and a red will be produced, which yields the sensation of red only, untinged with either yellow or blue. Take a spectral green, which is also slightly yellow, and treat it in the same way. If we now mix the absolutely pure red with the absolutely pure green, white is produced, not yellow. And now we can understand why spectral red and spectral green can be made to form yellow. For both the red and the green, which, when mixed, form yellow, when separate give the secondary sensation of yellow in addition to that of their principal colour. Thus, when mixed, the pure red annihilates the pure green, and yellow only remains. Measured by this standard, the primary colour sensations fall into two groups, in which each colour is complementary to the other. Firstly, red and green, from which the secondary sensations of yellow and blue are absent; and secondly, yellow and blue, which do not give the secondary sensations of either red or green.

Colour-blindness is brought in to support the Young-Helmholtz theory, but the author has obviously not had the opportunity of investigating many cases of this affection. He speaks of green-blindness, in which the sensations of red and violet are present, but not that of green, and of red-blindness, in which the sensations of green and violet are present, but not that of red; and gives measurements to show that in the latter class of cases the spectrum is shortened.

[1] "Die Grundempfindungen u. ihre Intensitäts-Vertheilung im Spectrum," *Sitzb. d. k. preuss. Akad. d. Wissenschaft. zu Berlin*, xxxix., 1886. Hering has since shown, by investigating a similar case of total colour-blindness how closely the curve of luminosity agrees with that given by Hillebrand. The treatment of this interesting case has not yet been

Digitized by Google

Now, Hering[1] has particularly investigated this portion of the subject, and explains the existence of two forms of colour-blindness as follows. He finds that persons with a normal colour-vision can be divided into two groups. The one class perceive yellow, the other blue, with exceptional ease, probably owing to a difference in the pigmentation of the media of the eye. The difference between the two groups is best seen with spectral green; for a green can be found which appears at the same time yellow-green to the one, blue-green to the other. To an observer with strong yellow vision, almost the whole of spectral red appears to be tinged with yellow, whilst a member of the second group, whose strong sense of blue prevents his seeing the yellow, pronounces the greater part to be pure red. Thus, the pure red and the pure blue are radically different colours for the two groups. Now, it is found that the pure red and the pure green formed for an observer with a strong sense of yellow appear grey to one who is what is called green-blind; whilst, on the other hand, the pure red or the pure green of the observer with a strong blue sense appears colourless to one who is red-blind. A red which is invisible to one who is "red-blind" is evidently coloured to a patient who is green blind, and he speaks of the colour he sees as red. But if a minute proportion of blue is added, the red gradually becomes purer until it becomes free from yellow to those of us who have a strong yellow sense. As the red becomes purer, our green-blind patient complains that the "red" is fading, and when finally the red is quite pure he matches the colour he sees with a grey, and says that the colour has gone. Thus, there is no fundamental difference between the red- and the green-blind. Neither group can perceive red or green. The only difference between them is one which we find amongst normal-sighted persons—namely, a different visual acuity for yellow and blue. The "red" of the green-blind is in reality the secondary sensation of yellow yielded by almost all the reds in nature, differing from the ordinary yellow in its limited power of exciting white. This peculiar yellow he has learnt to associate with what others around him call red, and he only betrays his affliction when all yellow is eliminated from the colour he calls red. Thus, a consideration of colour-blindness again leads us to throw red and green, blue and yellow, together into two groups as primary colour sensations.

Simultaneous contrast is touched on very superficially, and successive contrast is scarcely mentioned, yet the author again grasps at the three-colour theory to explain the few phenomena he mentions. Yet it is notorious that the Young-Helmholtz theory fails to afford any adequate explanation of the phenomena of contrast. It was by an ingenious contrast experiment that Hering produced such a striking confirmation of his views before the Physiological Congress at Basle, and placed the three-colour theory in a dilemma from which its ablest exponents have not yet succeeded in extracting it.

In conclusion, the book before us is an admirable summary of a valuable series of experiments. We can scarcely imagine that it will appeal to the public in general. But it should be read by those who are interested in the phenomenon of colour-vision, and the fact that the author frankly accepts the three-colour theory and ignores the work of Hering does not, in our opinion, detract from its value. For the book thus becomes an admirable statement of the strongest portion of the physical theory of colour by one of the ablest of English physicists.

POSITIVE SCIENCE AND THE SPHINX.

Riddles of the Sphinx. A Study in the Philosophy of Evolution. By a Troglodyte. (London: Swan Sonnenschein, 1891.)

THESE be old old riddles that the Sphinx propounds and the Troglodyte attempts to guess, in the volume before us; none other, indeed, than the What, Whence, and Whither of man and of the world. There have been other guesses in the past, there will be other guesses while time lasts; each guesser thinks his own guess nearer the true answer than any other; his neighbours mostly smile, unless his guess chances to be something like their own; and the Sphinx looks on with stony stare, imperturbable, giving no hints.

So soon as man, as man, looked out upon the world, and began dimly to realize the first personal pronoun, the nascent reason, or, if the phrase be preferred, intellectual faculty, demanded, for the first time in the history of the development of consciousness, an explanation. Man, then as now the chief centre of interest to man, must thenceforward not only live and act, but must seek to explain his life, and his activity. Yesterday the tribe-chief went forth a living man, feared by all: to-day his body is brought back, helpless, lifeless, and a hog spurns it with his snout. How account for this? How explain this change? Something there was about the man yesterday which made him totally different from the mere mass of clay that to-day already needs hustling out of sight. That something, call it soul, spirit, energy, life, what you will, has departed. Whither has it gone?

This question, eminently natural, almost inevitable, opened the way for reason's first blunder to enter and to become a fruitful mother of children. Reason, in the exercise of the new-born analytic faculty, distinguished between the mere body and the informing something through which it was a living body; between the material substance and the spirit-energy which was associated with that substance during life. But reason also jumped to the conclusion that what were distinguishable in thought were also capable of separate existence in fact. The matter remains in the corpse, but the something, the spirit-energy, has escaped, to lead a distinct and independent existence. In justification of this conclusion the phenomena of dreams were no doubt adduced as evidence. While the chief's body was lying stark and stiff, his true self, his spirit-energy, appeared by night to more than one of his chosen followers. Thus the dream seemed to support the false conclusion of the nascent reason, which had not yet learnt to distinguish without dividing.

It has cost positive science much labour, and not a few hard blows, to establish, by detailed work in physical science, biology, neurology, and psychology, the ille-

Digitized by Google

gitimacy of this conclusion. Now we distinguish further, but no longer divide. We distinguish between the material substance of the body and the energy of molecular motion during life; and, further, between the molecular motion of the grey matter of the cerebral hemispheres and the concomitant manifestation of consciousness. But although consciousness is distinguishable from molecular energy (and the distinction is absolute), it is not, so far as positive science can say, divisible therefrom. No physicist holds that the special modes of energy—we mean the particular groupings and interactions of energy—which characterize the functioning of a man's brain, escape from the molecules at death, and henceforward persist divorced from matter. We cannot, however, add that no psychologist holds an analogous doctrine concerning consciousness. But we contend that no psychologist is justified *on positive grounds* in holding such a view. That something called soul or spirit escapes from a man's body at death, and henceforward persists, divorced alike from matter and energy, is a view to which positive science as such gives no support. It is held by those who hold it on quite other grounds. The conclusion to which positive science points (and we include among positive sciences psychology, which deals with consciousness as existent) is that consciousness, though distinguishable from energy, is known only in association with certain forms of energy in organic tissues.

But this is a conclusion which is ignored by the Troglodyte. He professes to give us a "philosophy of evolution" which he himself describes as "the first perhaps which accepts without reserve the data of modern science." His theory of a Transcendental Ego; his suggestion that "matter is an admirably calculated machinery for regulating, limiting, and restraining the consciousness which it encases"; his conception of a graduated immortality, from that of an amœba up to that of man; his attempted rehabilitation of the view that force-atoms are monads "endowed with something like intelligence, and thus enabled to keep their positions with respect to one another"; all this, and much besides, seems to us completely off the lines of modern scientific advance.

But it may be said that such conceptions, though unnecessary for positive science, may be necessary for a philosophy which endeavours to go beyond and get behind science. In reply to this we can only say that we regard such conceptions as not only unnecessary to positive science, but unwarrantable intrusions into her domain. They form part of a different scheme of thought. The muddling together of positive and metaphysical conceptions is provocative of nothing but confusion and bad temper.

The introductory chapters of his first book, in which the author attempts to hound on positive science from agnosticism, through universal scepticism, to a gloomy pessimism, seem to us laboured and inconclusive, though there are incidental positions here and elsewhere with which we are in complete accord. With dogmatic Agnosticism and the Cult of the Unknowable (capital letters indispensable) we have but little sympathy. But this is no necessary part of the attitude of positive science, which seems to us briefly as follows. In the first place its followers take their start from the measurable and verifiable base-line of perceptual experience, from the ordinary facts of daily observation; and they utterly refuse, at this stage of the inquiry, to listen to the metaphysicians who hoot from their cloud-land, "But you haven't yet proved the existence of matter, or explained how it is possible to perceive or know anything at all." Starting, then, from the base-line of perceptual experience, they analyze phenomena, digging down by wise abstraction and the ignoring of unessentials, to deeper and deeper concepts, until they arrive at those universal abstracts which cannot be got rid of in thought without reaching nonentity. Happy they who in this procedure escape the analyst's fallacy—the supposition that the results of abstraction have a fuller reality than the phenomena with which they started. The analyst needs often to be reminded that the perceptual rose, with its delicate scent, its rich colour, its soft petals, is certainly not less real than the vibrating molecules which remain to his thought when, as physicist, he has stripped it of all its own peculiar charms.

Thus positive science in its deepest analysis brings us down to matter, and energy, and consciousness. If a number of metaphysical questions are intruded at all sorts of stages during this process, the result will be such confusion as the Troglodyte unconsciously exemplifies in his chapter on scepticism, a chapter in which some stress is laid on, and some capital made out of, the false psychological conclusion that conceptions cannot be derived from experience. Should the author ever come to grasp that the law of psychogenesis is one and indivisible, and sweeps through perceptual and conceptual processes alike, he will have to rewrite much of the "Riddles of the Sphinx." But, as he himself tells us, "the minds of most men are fortresses impenetrable to the most obvious fact, unless it can open up a correspondence with some of the prejudices within."

When positive science has dug down to basal conceptions, then, and not till then, in logical order (but, of course, far earlier in historical order) arises the question, "But how does it all come about? What is the origin and meaning of it?" We quite agree with the Troglodyte that this question *must* arise in the mind of every man in so far as he is a thinking man. The question, "How does it all come about?" however, presents two faces. It may mean, "How can we explain the fact of *knowing?*" And the solution of this problem is, we agree with Mr. Shadworth Hodgson in maintaining, the true business of philosophy. But even supposing that philosophy explains in some sense the process of knowing, there still remains the question in its further aspect, "But how does it all come about?" To this question, positive science as such answers, or should answer, humbly, and with no parade of capital letters, "I do not know."

And is that the end of the matter? So far as positive science at present goes, Yes. But man, the questioner, still remains; and Reason, true to her first impulse, still demands an explanation. Of the explanation afforded by revelation this is not the place to speak. But, quite apart from the fact of revelation, the explanation said to be revealed still stands as a product of the human mind. And he is a bold man, if not a foolish, who, having regard to the past history of human thought on the question, lightly sets aside the conception of a *Causa causarum* to whom we may attribute *symbolically* all the higher

Digitized by Google

attributes of man ; not because personality, wisdom, love (the symbols we employ), can truly describe or define that which passes man's comprehension, but because being man we can no other. Man alone in the organic world is capable of ideals, and for generations the name of God has stood for man's central ideal of power and perfection. And it seems to us that the sum and substance of positive criticism as applied to man's conceptions of that which admittedly lies beyond the reach of positive science comes to this: "You must frankly acknowledge and confess that such conceptions are symbolic and ideal." But if symbolic and ideal we must expect the symbolism to be variable in different ages, among different peoples, and even in different individuals. Hence (apart from revelation) the only indefensible attitude is that of inelastic dogmatism, positive or negative.

In conclusion, we may say that the "Riddles of the Sphinx" are in this work treated with considerable, though frequently misguided, power. The conception of evolution as a tendency towards an ideal of perfect individuals in a perfect society is good, and is in parts well worked out. That many will be found to acquiesce in the author's solutions of the old problems of life we think exceedingly doubtful. Nor do we think that the solutions will prove of lasting value. It is futile to attempt to preserve the new wine of positive science in the old bottles of prescientific metaphysics. The new wine must be preserved in new bottles. In other words, a new metaphysics must be and is being elaborated, in special relation to the newer aspects of scientific thought.

C. LL. M.

ANALYTICAL METHODS OF AGRICULTURAL CHEMISTS.

Proceedings of the Association of Official Agricultural Chemists, 1890. (Washington : United States Department of Agriculture.)

THIS is a Report of the Seventh Annual Convention of the Association, under the Presidentship of Mr. M. A. Scovell, and with Mr. H. W. Wiley as Secretary. The objects of the Association are to secure uniformity and accuracy of methods, results, and modes of statements of analyses of manures, soils, cattle foods, dairy products, and other materials connected with agricultural industry; and to afford opportunity for the discussion of matters of interest to agricultural chemists. In the words of a past President, it aims at laying "a foundation so solid, that every Court in this land must respect its conclusions, and every analytical chemist, whether he lives in this country or elsewhere, must be forced either to practice or admit the advantages and correctness of our system of analyses." A study of the programme and of the proceedings shows that the objects have been most carefully and conscientiously kept in view, and that all the working members have been most thoroughly imbued with the spirit of the Association.

The reports submitted for the consideration of the meetings, all drawn up by experts, and incorporating the work of many members, were as follows: on the determination of nitrogen ; on analysis of dairy products ; on analysis of potash ; on analysis of cattle foods ; on analysis of sugar ; on analysis of phosphoric acid ; on analysis of fermented liquors ; and a report of a Committee on foods and feeding-stuffs.

As an example : for the report on the determination of nitrogen in manures, three samples, containing nitrogen in different states of combination, were prepared, and sent to the members for analysis by various official methods. Twenty-two reported the results obtained by Kjeldahl's method on one sample, the same number the results of Kjeldahl's method modified for nitrates on two samples, and a less number gave results by the Ruffle method, the soda-lime method, and Dumas's method on one or more of the samples. The whole of the results are collated, with the remarks of the analysts thereon, so that data are obtained for testing the accuracy of the methods under various conditions, and eliminating personal factors. Various suggestions for the improvement or simplification of the processes are made and discussed, and some of them recommended for systematic trial during next year. Similar good work is done for the other Committees.

The remarks of the Committee on ways and means for securing more thorough chemical study of foods and feeding-stuffs, are particularly worthy of attention, pointing out, as they do, the deficiencies in present methods of analysis, and the absolute necessity of more exact methods and more accurate study of the proximate principles contained in foods, and of their physiological value. As a contribution towards this knowledge, Mr. W. E. Stone sends a paper on the occurrences and estimation of the pentaglucoses in feeding-stuffs, in which he shows that bodies yielding furfurol, and therefore presumably pentaglucoses, are present in grass, straw, linseed meal, and a great many other feeding-stuffs. Among the points which are noticed, and which should be known to all analysts, is the fact that cotton-seed meal, often used in mixed manures in the Southern States, is completely soluble in nitric acid with a little hydrochloric acid, but that the solution does not yield all its phosphoric acid to ammonium molybdate.

Should such a Bill as that introduced by Mr. Channing, for the better prevention of the adulteration of manures and feeding-stuffs in this country, ever become law—and the Government has promised to take up the matter—the formation of such an Association of Official Agricultural and Analytical Chemists in this country would be almost a necessity, and it seems that the Institute of Chemistry is the proper body to arrange the organization of such an Association.

GEOLOGICAL RAMBLES ROUND ABOUT LONDON.

Hand-book of the London Geological Field Class. By Prof. H. G. Seeley, F.R.S. (London: G. Philip and Son, 1891.)

THIS little book is a record of excursions similar in some respects to those collected in the volume of Geological Excursions which was noticed in these columns on June 18 (p. 149). But there are points of difference. This hand-book deals with a more limited area, being practically restricted to the south-east of England; it has a purpose more definitely educational. The latter may

Digitized by Google

be described in a few sentences extracted from the preface: —

"This Society exists to teach the elements of Physical Geography and Geology direct from Nature without preliminary study from books. . . . The field work has been led up to by short courses of winter lectures given in London, designed to connect together the observations to be made in the succeeding summer, and to connect the geology of the district to be examined with that of other areas."

The excursions are described in the notes written by students in the field; the lectures are reported (from shorthand notes) by Mr. White, one of the class. As regards the former, Prof. Seeley states that "students have been free to report what they saw and what they heard, and they have severally written in their own ways both as to length and language used." The lectures also "were not constructed with a view to being reported, nor were the reports written out with a view to being printed." Prof. Seeley has, however, "read the proof to remove serious inaccuracies." The lectures need no apology, for they are excellent examples of that clear and suggestive method of teaching of which Prof. Seeley is a master. The reports of the excursions also acquire a certain freshness as recording the impressions of novices, and may on that account be even more helpful to beginners than if they had been written by more experienced observers. One or two inaccuracies, however, appear to have escaped the Professor's watchful eye. Is not the statement on p. 18, relating to the presence of *Paludina* and *Unio* in such Wealden Limestones as the Petworth Marble, a little misleading? for it implies that the latter genus is common in these deposits, which, we believe, is not the case. A sentence on p. 29 suggests that "enormous pressure" is requisite to convert a sandstone into a quartzite. Very probably this would be the result, but there are not a few quartzites which show no signs of having been specially subjected to pressure. Also, it is hardly correct to call Lydian stone an altered sandstone. Again, more than once it is intimated that gneiss and crystalline schists occur in Belgium. This, if the terms be used in their ordinary sense, is incorrect; and even the porphyroids and amphibolites, and the abnormal rocks of the Bastogne district, the vague descriptions of which may have given rise to this misconception, are of extremely limited extent. But these are very trifling blemishes, which can be readily removed in a second edition. The book will be of great use to all students, living in or about London, in helping them to use their eyes; and most of all because, to quote Prof. Seeley's words, "It here and there touches upon problems which are not usually presented to beginners." But, as he rightly urges, these problems—namely, the application of stratigraphy to the elucidation of the physical geology of past epochs—"should never be absent from the mind of anyone who considers geological facts in the field."

T. G. B.

OUR BOOK SHELF.

Katalog der Bibliothek der Deutschen Seewarte zu Hamburg. (Hamburg, 1890.)

VARIOUS notices have from time to time appeared in NATURE relating to the German Naval Observatory at Hamburg, describing the building, its equipment of instruments, and the important work which is carried on there chiefly in the interests of the German Imperial and mercantile navies.

As this institution is possessed of a library containing some 10,660 works, it has for some time past been a matter of urgent necessity that an accurate and well-considered form of Catalogue should be printed and published. The required book was completed last year, and is now available.

This Catalogue shows that the library contains a large proportion of works either directly of a naval character, or bearing upon naval matters, whilst several other branches of science are fairly represented.

As might be expected, meteorology holds the first place of importance, and amongst the 2769 works on this subject are a large proportion of Dove's writings. Indeed, it seems worthy of note that Dove's library, which occupied him many years in collecting, may now be found at the German Naval Observatory. Turning to the division of the Catalogue on physics, 1617 works will be found; on magnetism and electricity, 974; whilst other subjects, such as navigation, hydrography, and construction of ships are well cared for.

Although the books and papers mentioned in this Catalogue are generally printed in the language adopted by their authors, a translation into German of several works of interest is also placed side by side with the original.

In conclusion it may be remarked that although there is nothing specially new in the arrangement of this book, it is well worthy of the time and energy which have evidently been spent in bringing the work to its present state.

Scientific Results of the Second Yarkand Mission; based upon the Collections and Notes of the late Ferdinand Stoliczka, Ph.D.—Coleoptera. By H. W. Bates, F.R.S., J. B. Baly, D. Sharp, F.R.S., O. Janson, and F. Bates. Pp. 1–79 and 2 Plates. (Calcutta: Published by order of the Government of India, 1890.)

THIS, the twelfth part issued, all but one of which deal with zoology, contains an enumeration of 207 species of Coleoptera. These species belong to the following families:—Cicindelidæ (4), Carabidæ (60), Longicornia (5), Phytophaga (25), Haliplidæ (1), Dytiscidæ (8), Gyrinidæ (1), Hydrophilidæ (3), Staphylinidæ (9), Scarabæidæ (38), Cetoniidæ (3), and Heteromera (50). Diagnoses or descriptions of all the new genera and species were published more than ten years ago, and the only additional information contained in this part is a list of species, in addition to, in some cases, fuller descriptions of the novelties. In the portions contributed by Mr. H. W. Bates and Dr. Baly, both of whom, however, give some particulars regarding geographical distribution, the references to the published diagnoses are given; but in Dr. Sharp's and Mr. F. Bates's contributions, many of the genera and species are mentioned as new, though diagnoses of the whole of them were published in 1878 or 1879—the former in the Journal of the Asiatic Society of Bengal, xlvii. Part 2 (1878), the latter in *Cistula Entomologica*, ii. (February 1879). The two plates include 44 figures—Carabidæ (17), Longicornia (5), and Heteromera (22). On the cover, and also on p. 37, the name "Hydrophilidæ" is misprinted "Hydroptilidæ." The Hydroptilidæ do not belong to the order Coleoptera at all, but to the Neuroptera! It is to be regretted that a delay, the cause of which is not explained, of more than ten years, has occurred in the publication of the "Part" dealing with the Coleoptera, as works of this kind upon the beetle fauna of little-known districts are always of the highest value, more particularly in the matter of geographical distribution. No systematic work upon the Coleopterous fauna of India has

Digitized by Google

yet been published, and even a fragment like the present, containing a list of the species of a neighbouring region, is a welcome addition to our knowledge. Four other "Parts" have been issued on the Insecta—the "Neuroptera" and "Hymenoptera" (both in 1878), and the "Lepidoptera" and "Rhynchota" (both in 1879); the last Part of the whole series being the "Araneidea" (1885).

Popular Astronomy. By Sir George B. Airy, K.C.B. Seventh Edition. Revised by H. H. Turner, M.A., B.Sc. (London: Macmillan and Co., 1891.)

ALTHOUGH our astronomical knowledge has been enormously extended since the lectures forming the basis of this well-known book were delivered (1848), Mr. Turner has not found it necessary to make any very considerable revision, for the reason that the advances have been chiefly on the chemical and physical sides. Still, in the lapse of time, methods of observation have been improved, and accounts of these find a place in Mr. Turner's notes. Among these are short descriptions of the chronograph and the new "electrical controls" for the driving-clocks of equatorials. One of the most noteworthy points brought out in the new edition, however, is the modern estimate of the value of observations of the transit of Venus as a means of determining the solar parallax. It was formerly supposed that this would be one of the best methods, but the difficulties encountered in 1874 and 1882 prevented observations of the necessary degree of accuracy; and now most astronomers are of opinion that this method can never give more than an approximation to the truth. Numerous minor additions have also been judiciously made.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Force and Determinism.

"THE relation between force, which is a mechanical thing, and will or life, or whatever it is, which is a psychological thing"—a relation which, as Dr. Lodge rightly says, "demands investigation"—presents itself to some of us as follows.

When a stimulus received by an organism gives rise to a response, however particular to the individual respondent, there are (1) a number of complex but determinate molecular changes in the organic tissues; and (2), accompanying some of these changes, certain psychological states. Are these psychological states produced by the molecular changes? or are the molecular changes produced or in any way guided by the psychological states? Neither the one nor the other. The molecular changes and the psychological states are different aspects of the same occurrences. In other words, they are distinguishable (and the distinction is absolute), but not divisible.

"The energy displayed by a gang of navvies is not theirs, but their victuals'; they simply direct it." In physiological language it is the outcome of the proper functioning of their cerebral control-centres. Now we believe that, although we can at present by no means adequately explain them, all the molecular occurrences within the organism, forming, as we believe they do, an orderly and determinate sequence between stimulus and response, whether they involve force or energy, are of such a nature as to be explicable in physical and physiological terms. The fact that certain phases of the sequence have also a subjective or psychological aspect does not, it is held, justify us in changing our point of view, and ignoring the distinction between the psychology and the physiology of the process.

Now to say that mind, or will, or consciousness directs the organic energy along a definite path we regard as incorrect, because it ignores a distinction which we hold to be valid and valuable, and conducive to clear thinking on these difficult subjects. But we have no such objection to the statement that the energy is guided by molecular forces which have for their subjective aspect certain states of consciousness. To unscientific folk this may sound mere quibbling; but to physicists, who have done so much to teach us the vital importance of accurate language for clear thinking, we look for support in drawing this distinction, unless the distinction can be shown to be either invalid or useless.

This distinction between force, energy, and the physical series (what I have elsewhere spoken of as *kinesis*) on the one hand, and thought, consciousness, and the psychical series (what I have elsewhere spoken of as *metakinesis*) on the other hand, we hold to be absolute; while at the same time we hold that consciousness is indivisible from particular (neural) modes of kinesis. And this distinction we hold to be especially valuable when questions of the origin and development of consciousness are under consideration. This may, perhaps, best be expressed by a diagram.

Now, looked at from above, this wriggle is supposed to represent the development, from simple forms of molecular transactions, of that complex form of kinesis which we call neurosis. From this point of view, all is force and energy or kinesis, and can become nothing else. Looked at from below, we have the development of consciousness. From what? We must not say from lower forms of energy or kinesis, because that involves jumping across the line, or, in other words, ignoring the distinction. From what, then? From those lower forms of "something-which-is-not-yet-consciousness-but-which-may-develop-into-consciousness," for which I have ventured to coin the term metakinesis.

I have elsewhere endeavoured to show that this view is not open to the objection that, since the kinetic sequence is a continuous and determinate one, consciousness is merely a by-product, and that an unconscious Darwin might have written and influenced the conduct of unconscious Englishmen. For consciousness, though it is distinguishable from, is, according to the hypothesis, no less inseparable from, certain complex modes of the kinetic process. As the world is constituted, such supposed kineses, separated from their metakinetic aspect, would not be the same kineses but something altogether different. In other words, it is with certain molecular transactions which have also a conscious aspect that, in the world of living beings of which we have practical knowledge, we have to deal.

It is essential that physicists and psychologists should work hand in hand. Both are endeavouring to explain the phenomena on positive lines. And if there is anything in the views that I have briefly sketched in the preceding paragraphs which runs counter to the conclusions of physics, it must go by the board, and give place to a more widely-consistent conclusion, to which physics, speaking with the voice of authority in its own special province, can give a cordial assent. C. LLOYD MORGAN.

I AM afraid that, as Prof. Lodge has accepted my "middle paragraph" so easily, he has failed to appreciate its point. For, if that paragraph is correct, the Professor's assertion, "Force is certainly necessary to direct the motion of matter," is only a truism, similar to the important geometrical theorem, "In any right-angled triangle, one angle is equal to 90°." On the other hand, Dr. Croll's assertion, to the effect that guidance is effected by "determinism," and *not* by force, is a contradiction in terms. For, by definition, that which changes motion *is* force. If, therefore, Prof. Lodge's assertion has any real meaning, he must have some independent definition of "force," and I should very much like to know what that is.

Again, Prof. Lodge in no way answers "the crux in my last paragraph." Prof. Lloyd Morgan implies in his last letter that, in the case of the sun altering the direction of motion of the earth, no energy is expended. This is, of course, only approximately true; and even in the case of his twirling his stick round his finger and thumb, as the stick is elastic, its forces of cohesion in reality do some small amount of work. It is indeed true that, if two particles were once connected by an *absolutely* inextensible string, the cohesion of the string would do no work. But what I pointed out was that, in order to bring such

Digitized by Google

a string into action, it would be necessary to wait till two particles were moving on paths with a common normal—an occurrence which must be infinitely rare. When Prof. Lodge says "an infinite mass can absorb any amount of momentum, without receiving a trace of energy, &c.," he forgets that the term "infinite" is only relative, "an infinite mass" being one whose change of velocity (or kinetic energy) consequent on a given change of momentum is negligible *for the purpose in hand*. It would not, I imagine, suit Prof. Lodge's purpose to suppose psychic forces might do a *little* work, so long as it was only a *very little?*

May I remind him of the old paradox, "What would happen if an irresistible force were brought to bear against an immovable post?" EDWARD T. DIXON.

12 Barkston Mansions, South Kensington, July 24.

THE discussion on this topic has gained in clearness by Prof. Lodge's conceding that "the same question—What determines the direction of the transfer of energy?—may doubtless be asked in connection with inanimate activity; . . . but in neither case do I know the answer."

Perhaps some more precision may be attained by expressing the question in other words.

The principle of conservation of energy reigns over the *quantitative* relations of all processes in nature, but it does not give any explanation of the *qualitative* changes of those processes. These changes and their conditions must in every case be found out by special experience. But, nevertheless, they are, in every accessible case, found to be subjected to fixed laws. A given substance undergoes evaporation or chemical transformation—dependent on or necessarily bound up with changes of heat into energy of molecular motion, or into chemical energy, or *vice versâ*—at a distinct degree of temperature, or under distinct conditions of electrical action. Inexplicable as these transformations of quality or form of energy remain for us, there is nothing undetermined in them, neither have we any right to such a supposition for the qualitative changes going on in plants and animals—their quantitative relations being likewise governed by the principle of conservation of energy.

But there is another phase of the question. Some unknown material changes in the brain are connected with phenomena of consciousness. Nothing can be more fallacious than to consider consciousness as a form of energy, and to suppose it in a relation of equivalence to such forms. How it is, that what to our physical conception, or outer sense, are processes in the brain (which, as such, may be more clearly understood in future), are, at the same time, to our psychical conception, or inner sense, phenomena of consciousness, or acts of will, is a question beyond the domain of physical science, and capable of elucidation only by transcendental philosophy. Whoever wishes for more light here, must study the "Kritik der reinen Vernunft," especially the chapters "Von den Paralogismen" and "Die Antinomien."

Schopenhauer, and others after him, have considered our power of will, or our conscious directing of motion, as the key for all qualitative processes in nature, these being considered as, in their essence, acts of will. But this is cutting the knot by means of a metaphysical assumption. D. WETTERHAN.

Freiburg, Badenia, July 27.

IN reading over the remarks of Dr. Lodge and Prof. Morgan upon Dr. Croll's views as to the direction of force, it appears to me that both have missed the point. Dr. Croll did not mean that a force at right angles to another does no work, but simply alters the direction. His view is that the change of direction is not caused by a force. Dr. Lodge says it is, although he acknowledges that the second force does no work. Further, Dr. Croll says, with regard to the first force, that its direction is quite apart from the force. The force cannot direct itself. This is the crucial point before we get to a second force or to a right angle. I fully acknowledge the importance of Dr. Lodge's principle, but it is not simply the indorsement of Dr. Croll's idea.

Prof. Morgan thinks Dr. Croll's view no argument in favour of theism. It does not prove that mind can or does affect matter. Perhaps it does not directly prove this, but, within its range, it seems to me an effective reply to mechanical atheism. We see direction, and if this does not come from force it must come from some other source. We know of no other source but mind. To talk of mind affecting matter denies the essence of mind by which it is distinct from matter, and makes it a mechanical *ab extrâ*. But try to banish it and it will come in somewhere. "Tamen usque recurret."

Dr. Croll's position seems to me to affect the first law of motion. Uniform motion in a straight line is in no way connected essentially with force, if his view is correct.

Dr. Lodge's principle appears to affect the second law of motion, and also the doctrine of impact and transference of force.

Further, it affects gravity. Gravity is always at right angles to the first law of motion, and therefore gravity is not a force; for that can not be a force which never exercises force.

T. TRAVERS SHERLOCK.

Congregational Church, Smethwick, July 25.

Technical Education for Farmers, Farriers, and Engine-Drivers.

KNOWING that you take very great interest in the various questions relating to technical education, I may give you a few particulars of an experiment which the Devon County Agricultural Society recently made at its Exmouth meeting. Being desirous of giving farmers, farriers, and those generally interested in the welfare of horses, some information on the scientific principles which underlie a proper performance of the duties of the farrier, and the correct form and mode of attachment of horses' shoes; and also of giving farmers and engine-drivers some practical and scientific instructions on the working and care of steam-engines, the Society approached the County Council with a view to a grant in aid of their object. The proposal was very warmly taken up by Mr. Lethbridge and other gentlemen who are well known for their active interest in education and other matters important to the welfare of the county, and a grant was obtained.

The Society secured the services of Prof. F. Smith, head of the Army Veterinary School, Aldershot, and of Mr. W. Worby Beaumont, and by these gentlemen lectures were given on each of the three days of the Society's meeting at Exmouth. The weather was very unfavourable on two days, but notwithstanding this the attendance at the lectures was large, and on the second and third days was larger than was expected, and was fully up to the accommodation provided. The audiences were remarkably attentive and appreciative, and in every respect the experiment proved successful. Many who were sceptical before the lectures of their value to working men, became convinced that not only is it possible to give working men information which is useful in an important degree in their daily work, but that the men are themselves quick to appreciate its value. I may mention that on one of the days nearly two hundred shoeing-smiths and a large number of farmers attended the horse-shoeing lectures, and on one day seventy-eight engine-drivers entered for the lecture on the steam-engine, and there were also in attendance a large number of working and gentlemen farmers.

Totnes, July 29. JOHN L. WINTER.

THE ERUPTION OF VESUVIUS OF JUNE 7, 1891.

THE suggestion that I published in several newspapers has been fully confirmed—namely, that the second alternative type of eruptive character would be pursued by the volcano. Now for a period of over a month lava has continued to dribble forth, activity has returned to the central vent, and no great changes have occurred.

The throat of the volcano commenced to be cleared on June 9, the vapour forcing its way up from the crater bottom through the choke of loose materials, and rose above as a column carrying with it much dust; at the same time the powerful vapour blast issuing from the upper extremity of the lateral rift, of which mention is made in my first letter, soon stopped. Each day I was kept informed of the state of the volcano by the kindness of Messrs. Ferber and Treiber, the director and engineer respectively of the Vesuvian Railway.

On June 15 I considered it right to again visit the

Digitized by Google

mountain, and had the good fortune to be accompanied by Messrs. H. Elliot, A. Green, Linden, Newstead, and Treiber, several of whom are excellent photographers, so that with two of my own cameras we were able to make an extensive pictorial record of some very unique formations.

At the point of issue of the lava, at the junction of the foot of the great Vesuvian cone and the Atrio del Cavallo, the first lava had cooled sufficiently to walk over it, but beneath our feet could still be seen in a few holes the flowing lava. At the foot of the great cone, and extending for half way across the Atrio along the radius of the eruptive rent, as if this had continued so far, were a series of driblet cone fumaroles. We counted seven complete and well-formed examples, besides numerous abortive ones. Most were giving out intensely heated vapour, which was liberated from the lava flowing beneath, and which soon carbonized a piece of wood placed in it. Around the lips of the upper opening, hæmatite with fused chlorides of potash, soda, iron, copper, &c., were being condensed from the vapour, and trickling down the outer surface of the fumarole, consolidated as curious vari-coloured stalactites of very deliquescent nature.

The lava had first flowed towards the escarpment of Monte Somma in a fan-like manner, so that the eastern extremity reached that great natural section just beneath the Punta del Nasone. Still following the natural inclination of the ground, it turned to the west, and on June 15 was opposite dyke 16 (as marked on my large geological map just published, and on the dykes themselves), advancing at a very slow rate.

The lava is a vitreous and coarse-grained rock, especially in regard to the included leucite crystals, whilst the surface is, with one exceptional tongue, of the corded or "pahoehoe" type. This is due to the magma being one that has been simmering since January in the chimney of the volcano, so that most of its dissolved H_2O has been boiled off, and so allowing it to cool without the formation of scoria from the vapour that otherwise would escape after its exit. Leucite I have also demonstrated to be formed while the magma is simmering under low pressure with free escape for vapour in the upper part of the volcanic chimney.[1]

At the summit of the great cone the crumbling in of the edges was constantly going on, but the upper extremity of the lateral rift at the foot of the cone of eruption and at the summit of the great Vesuvian cone had nearly ceased to give forth vapour. Along the line of rent on the mountain side no fumaroles or other signs of activity were visible except quite at the foot, where those commence of which I have spoken.

Up till June 26 there was a struggle to clear the upper part of the volcanic chimney of the impeding materials, which were constantly being added to by the slips from the crater's edge; but on that evening a dull red glow was visible in the crater bottom, showing that a fairly clear passage had been temporarily made for the continuous escape of vapour, and also that the lava was at no very great depth from the summit of the volcano. This of course indicates that the lateral opening was insufficient to drain off much of the lava which occupies the chimney above the level of the lateral outlet. Had such evacuation really taken place, the eruption would have assumed enormous proportions, from the actual amount of lava above the tap, but more from frothing up of that below that level in consequence of the relief of pressure that in that case would occur. Of course, during all these days the ejection of dust with the smoke occurred, giving the latter that peculiar dark grey colour. Further destruction of the crater edge took place, so as to partly block the outlet, and it was not till our next visit that it again cleared.

On June 30 I again visited the crater, in company of my friend Mr. A. Green. All the summit of the great cone

[1] See H. J. J.-L., "Geol. M. Somma and Vesuvius," Q.J.G.S., vol. xl.; and "Relationship of the Structure of Igneous Rocks to the Conditions of their Formation," Scient. Proceed. R. Dublin Soc., vol. v., N.S.

Digitized by Google

was covered by a thick coating of dust and sand, upon the surface of which were the usual white and yellowish-green chloride crusts seen on such occasions, so rich in copper as to plate with that metal the iron nails of our boots. The crater had considerably enlarged, the edges were in an extremely unstable state, with often considerable strips marked off by cracks parallel to the free edge, so that, with a slight push by a stick, it was possible to detach large masses of the materials which form the sides of the crater in the recent cone of eruption. So dangerous were the edges, that it was but in two places that my experience indicated as being safe to approach and look over, and that even with several precautions; so that the fatal accident to Señor Silva Jardim, who lost his life here but a few hours after our departure, is not to be wondered at.

On looking down some 45 to 50 m. beneath us, we could see the glow from a mouth some 2 or 3 m. in diameter. The walls of the crater were concave, so that although overhanging at the top, yet a plumb-line let fall from the edge would strike the bottom of the cliff. The crater bottom was roughly plain, due to the combination of a talus all round, and an attempt at a cone encircling the main vent. It will be thus seen that the crater cavity was of the form of a convex-sided cylinder, or more simply barrel-shaped, with its upper diameter some 50 to 55 m.

With much difficulty we made our way around to the north side of the cone of eruption, which had now lost its usual loose scoria surface, which was buried beneath a thick coat of sand and dust, covered with a thin saline crust on its surface. The upper limit of the radial rift, which we were prevented from examining three weeks previously, on account of its giving out so much vapour as to constitute the temporary escape aperture of the volcano, had now become quiescent, so that we could fully examine it. Only a current of hot air was now issuing from it, but I was able to collect some fine masses of crystallized molysite and kremersite from its edges. Its average breadth was about 0·50 m., where it traversed old compact lava, but of course it disappeared as soon as it reached the looser materials. The real azimuth of its orientation, which we could now determine with greater accuracy than when we were walking over hot rock and enveloped in hot irritating vapours, proves to be, as it radiates away from the axis of Vesuvius, about 15° west of north. It curves then a little to the north, and near the foot of the great cone it again assumes nearly the same azimuth as at starting, an arrangement which is quite evident when the Vesuvian cone is regarded from the Punta del Nasone. From that, the highest point of Somma, the lower extremity of the rift lies a little to the right or west, and faces that part of the Somma ridge which corresponds to the upper extremity of the Vallone Cancherone.

In the forenoon of June 30 much dust had fallen at the lower railway station, of which we collected some bagsful. It is the usual fine sandy material of these eruptions, and consists of the pulverized materials of the cone of eruption.

Having passed the night at the lower railway station, the next day we crossed the Atrio, ascended to the western extremity of the ridge of Somma, and followed it along so as to get a general bird's-eye view of the whole scene of the eruption, and take photographs of the more important points. As one stands on the Punta del Nasone and embraces that magnificent view of Vesuvius and the Atrio del Cavallo, one sees at their feet the new lava-stream in the form of the letter ⌊, the horizontal portion of which is still being prolonged down the Atrio towards the Fossa della Vetrana. In the middle of the ridge we found a thin coating of fine red dust which had reached thus far from the crater. Much of the Atrio was also covered by the same material. Scaling the cliff face just beyond the Cognulo di Ottajano to the Atrio del Cavallo, we again visited the lower point of the outburst. Most of the beautiful fumaroles were in a state of ruin, and lined by good-sized crystals of hæmatite and mixed chloride crusts. Here the lava was quite solid, though at one point was a hole, some 50 m. from the base of the great cone, where we could see the molten rock flowing lazily along about a metre beneath our feet. The lava at the end of the flow was making considerable progress to the westwards, and stood opposite dyke 13.

Since then, few changes have taken place in the mountain: the crater still gets larger, dust is thrown out, and the lava descends. These phenomena are capable of continuing for months if the drainage opening does not enlarge.

As the eruption progresses, I will send you further details. H. J. JOHNSTON-LAVIS.

THE PRODUCTION OF MUSICAL NOTES FROM NON-MUSICAL SANDS.

THAT I have succeeded in producing musical notes from sand that was never before musical, and am also able to produce similar results from certain mute or "killed" musical sands which have been temporarily deprived of their musical properties, has already been announced in the *Chemical News* (vol. lxiv. No. 1650).

It is not necessary now to give the details of the numerous experiments which led up to this discovery; it will be, perhaps, sufficient for present purposes, to state that in November 1888 I published a paper[1] in which I propounded a theory to account for the cause of musical sounds issuing from certain sands. After giving various reasons for my conclusions, I said:—"It occurred to me, then, that the music from sand was simply the result of the *rubbing together* of the surfaces of millions of perfectly clean grains of quartz, free from angularities, roughness, or adherent matter, in the form of clinging fragments investing the grains, and that these microlithic emissions of sound, though individually inaudible, might in combination produce a note sufficiently powerful to be sensible to us."

Having described numerous experiments, and drawn attention to the hopeful results obtained from the "millet-seed" sand, my paper concluded with the following:—"From what I have now told you, I think we may conclude that music may be produced from sand if (1) the grains are rounded, polished, and free from fine fragments; (2) if they have a sufficient amount of 'play' to enable them to slide one against the other; (3) if the grains are perfectly clean; and (4) if they possess a certain degree of uniformity in size, and are within a certain range of size."

On June 20 last I visited Studland Bay for the purpose of carrying out some new experiments. I found that the musical patch emitted tones louder and more pronounced than I had ever heard them there before. The best results were obtained by drawing a thick deal rod, on to the end of which I had fixed a resonator, over the surface of the sand; sounds produced in this way were heard unmistakably for a considerable distance. The patch averaged 7½ yards in width, and ran parallel with the trend of the shore for some hundreds of yards. The sand on the sea side of the patch was fine, and emitted notes of a high pitch; that on the land side was coarse, and emitted notes of a lower pitch. The rod drawn across the patch gave, therefore, a great variety of pitch. Many other interesting facts cannot now be referred to, but it is important to state that some of this sand, when taken off the patch, and struck in a box, gave out notes as it did *in situ*. On trying this sand subsequently at home, the *coarse* emitted distinct

[1] Read before the Bournemouth Society of Natural Science.

Digitized by Google

notes of a low pitch, but the fine was mute. This was, so far as I know, the first time that the Studland sand had been musical *off the patch*.

According to my theory, if the number of grains with polished surfaces could be increased in this fine sand, the number of vibrations would increase also, and so intensify the note, and cause it to become audible; this could only be done, however, by introducing a certain percentage of grains fulfilling the required conditions. To obtain such grains and to introduce them gradually until the necessary number should have been added, would have been a tedious process; and it occurred to me then that the same result might be obtained if the sand were struck in a vessel with a hard and polished interior. I placed, therefore, this fine sand in a teacup, and on striking it, found that it emitted a high, shrill note (A in *altissimo*), which was far more intense than that given when it formed a part of the patch.

When polished grains of sand are in contact with the sides and bottom of a glazed porcelain vessel, it is obvious that there are numerous points of contact between two polished surfaces—the sand grains and the vessel—and that on striking the surface of the sand, the friction necessary to produce the vibrations of a musical note is induced between these points.

This I *proved* by placing the same sand in various vessels with rough interiors, and by lining these glazed or polished vessels with silk, &c., but in no case would this sand emit notes unless the grains were in direct contact with the glazed or polished surfaces. This peculiarity is not in any way dependent upon the sonorous properties of the vessel used, for it may be "deadened" with impunity, and the note will remain unaltered.

The results of numerous experiments show that musical sand of the Eigg type—*i.e.* sand possessing in great perfection the physical conditions necessary for the production of music—will be musical in receptacles of whatever composition or form, though in some of these it emits notes "under protest" only.[1]

Those sands which are of the Studland Bay type—*i.e.* having the necessary physical conditions less perfectly developed, and are usually mute except *in situ*—will emit music only in vessels possessing hard and glazed interiors, and, as a rule, of a certain form; while some of the more "sulky" types of sand not only need a vessel of hard and glazed interior, and definite form, but also require a box, or small pedestal of wood (which I call a "coaxer"), on which this vessel must stand before the notes emitted become audible. A "sulky" sand was rendered far more musical by being sifted, washed, and boiled, giving out, after this treatment, notes without the aid of the "coaxer."[2]

After discovering what could be done with such simple apparatus, it occurred to me to try, under similar conditions, some of my abandoned sands—those unmusical sands that had been, during a period of four or five years, treated unsuccessfully for music.

One sand (an iron-sand composed of more or less polished grains, quartz, and much dust formed of denser minerals) gave a very hopeful "swish" (explained in my paper of 1888) in a certain porcelain vessel, and from this—by (1) sifting in sieves, to eliminate the fine material, and to insure uniformity in size of grain; (2) rolling down an inclined plane of frosted glass, to separate the rounded grains from the angular quartz; and (3) boiling in dilute hydrochloric acid, to cleanse the surfaces—I succeeded in producing a sand that, in certain glazed vessels, emits musical notes as clear as those emitted from any of my musical sands but that of Eigg. This sand gives F in *altissimo*, but it very soon becomes "killed" because of the fine dust and loss of polish that is the inevitable result of the attrition of the grains. There remains but one thing to be done, and that is to produce a sand which, like that of Eigg, will be musical in almost any receptacle, and I have reason now to think that this will not be very difficult.

It has not been possible here to record more than the merest outline of what has been done, or to give instances of the interesting *capriciousness* of these sands; it should be understood, however, that no *ordinary* beach or cliff sand has the slightest inclination to "sing" under any of the "coaxing" methods at present known to me.

CECIL CARUS-WILSON.

[1] When musical sands sound "under protest" they give out high, shrill notes. The smallest quantity of musical sand from which I can obtain a true note is a thimbleful of the Eigg sand. Small quantities emit notes of a high pitch.

[2] Many musical sands are quickly "killed" by constant striking, because the harder minerals present abrade the softer as they rub together, and this forms a fine dust.

NOTES.

SIR MICHAEL HICKS-BEACH, who previously gave a negative answer to the request made by the Executive Committee of the British Institute of Preventive Medicine, having reconsidered his decision, has now granted the required license to register the Institution as a Limited Liability Company, with the omission of the word "Limited." The license, however, is not to be construed as expressing approval by the President of the Board of Trade of experiments on animals, or in any way affecting the exercise by the Secretary of State of his discretionary powers to grant a vivisection license to the proposed Institute. The articles of association have been signed, and the Institute is now duly registered. The following gentlemen have already expressed their willingness to serve on the Council: Sir Joseph Lister, Chairman, Sir Charles A. Cameron, Mr. Watson Cheyne, Prof. Michael Foster, Prof. Greenfield, Prof. Victor Horsley, Sir William Roberts, Sir Henry Roscoe, Prof. Roy, Prof. Burdon-Sanderson, Dr. Pye-Smith. Dr. Armand Ruffer, of 19 Iddesleigh Mansions, Westminster, S.W., will act as honorary secretary until the first meeting of the Council.

THE graduation ceremony at the close of the summer session of the University of Edinburgh was held on Monday. Principal Sir William Muir, Vice-Chancellor, presided. Prof. Kirkpatrick presented for the honorary degree of Doctor of Laws Colonel Sir Colin Campbell Scott Moncrieff, K.C.M.G., C.S.I., R.E., remarking that, through his work as chief officer of the irrigation works of the Nile, it could be said that Sir Colin had created a greater and an infinitely freer, happier, and more prosperous Egypt than it was before. As a gallant officer, a distinguished man of science, a statesman of high merit, and, above all, as a benefactor of his fellow-creatures, Sir Colin was pre-eminently worthy of the highest of their academic honours. The honorary degree of Doctor of Law was then conferred *in absentiâ* on Prof. Simon Newcomb, Washington.

SIR JOSEPH FAYRER has been elected a Corresponding Member of the Royal Italian Society of Hygiene. Sir Joseph has also been promoted from the grade of Foreign Corresponding Member to that of Foreign Associate of the French Academy of Medicine.

PROF. DU BOIS-REYMOND, the distinguished physiologist of Berlin, has been awarded the Gold Medal for Science.

MR. J. E. KEELER has been elected Professor of Astrophysics in the Western University of Pennsylvania, and Director of the Allegheny Observatory. Mr. F. W. Very is associated with him as Adjunct Professor of Astronomy. It is expected that the Observatory will continue its researches on important problems in the domain of astro-physics.

IT is stated that Siam, following the example of Japan, is commencing to Europeanize her institutions. The founding of

Digitized by Google

a University has been decided upon, and Prof. Haase, of Königsberg (Germany), has accepted the appointment to the Chair of Physics.

THE last number of the *Rendiconti* of the Reale Accademia dei Lincei contains an account of the annual meeting held on June 9, at which the King of Italy was present. After the opening speech of the President, Brioschi, one of the chief features was an admirable address by Prof. Messedaglia on the Homeric uranology, with special reference to precession.

La Revue Scientifique of the 1st instant contains the address by M. Villemin, the President of the Tuberculosis Congress. It deals with recent researches. The results of the first Congress are also detailed by M. Petit, the General Secretary.

A FINAL meeting of the Committee of the Virchow Testimonial Fund took place on July 16, Sir James Paget, Bart., F.R.S., in the chair. The Treasurer gave an account of the moneys received, which amounted to about £175. It was resolved to send this sum to the General Treasurer of the Fund, and to present Prof. Virchow on the occasion of his birthday with an illuminated address, conveying to him the congratulations of the Committee and subscribers. This the Honorary Secretaries, Dr. Semon and Mr. Horsley, were directed personally to transmit to Berlin on the occasion of the celebration.

THE Essex County Council has appointed an Organizing Joint Committee, consisting of six members of their own body and six members of the Essex Field Club, to form a centre for supplying lecturers and teachers (with apparatus and materials), conducting examinations, and affording help and guidance to local bodies, in connection with the recent grants towards technical instruction. A grant of £900 has been made for these purposes. The members of the Committee are: (representing the County Council) Mr. E. N. Buxton, Mr. E. A. Fitch, Mr. J. H. Burrows, Mr. S. W. Squier, Mr. F. West, and Mr. W. B. Whittingham; (for the Essex Field Club) Prof. Boulger, Mr. F. Chancellor, Prof. R. Meldola, F.R.S., Sir Henry E. Roscoe, M.P., F.R.S., Mr. F. W. Rudler, and Mr. J. C. Shenstone. The Organizing Secretary to the Committee is Mr. W. Cole, 35 New Broad Street, E.C.

THE idea of "a British Museum of Portraits," to be executed by photography, was conceived as long ago as 1864 by Mr. James Glaisher, F.R.S., and brought before a meeting of the Council of the Amateur Photographic Association, of which the Prince of Wales is the President. The suggestion was cordially approved by the meeting, and photographs were taken in *carte de visite* size and deposited at the South Kensington Museum. At first, however, only fading silver prints were made, and these were so unsatisfactory that for some years the undertaking was held in abeyance. By the discovery and perfection of the process of permanent carbon printing, an opportunity has at length been afforded of resuming the prosecution of the work under infinitely more favourable conditions; and, as a result, a collection of excellent portraits is now being made by the Amateur Photographic Association. Already there are nearly 200 large permanent carbon portraits deposited in the Art Department at the South Kensington Museum, and about as many more are ready to be sent. These latter were on exhibition at a private view on Saturday last at 58 Pall Mall, S.W., the studio of Mr. Arthur J. Melhuish (Photographer Royal). They embrace some photographs of men of distinction in science, and are excellent both as likenesses and as specimens of photographic art. The conditions under which they are taken are, in fact, sufficiently exacting to insure the production of a faithful portrait, inasmuch as every portrait must be approved by the sitter and by the Standing Committee previous to its being placed in the South Kensington Museum. The undertaking is on a non-commercial basis, the photographs being taken for the purposes of this collection only, and not for publication, and no expense of any kind being incurred by the sitter. The invitations to sitters are issued under the authority of the Council.

THE Trustees of the Indian Museum, Calcutta, have just issued the second and concluding portion of a Catalogue of the specimens of Mammals contained in that Institution. The first volume of the Catalogue, compiled by Dr. John Anderson, the late Superintendent, was published in 1881. The present volume, which commences with the Rodents, has been prepared by Mr. W. L. Sclater, the present Deputy-Superintendent. The total number of specimens of Mammals contained in the Indian Museum, as is shown in the Catalogue, is 4872. These are referred to 590 species, of which, 276 are found within the limits of the Indian Empire, and the remainder are from elsewhere. As the Indian Museum contains many types of Blyth, Jerdon, and the older Indian authorities, the collection is one of considerable importance, and the Catalogue will be of much use to students of the group of Mammals.

FOR the first time for many years the *Journal für Ornithologie* has actually appeared within the month imprinted on the cover bearing the date of publication. English ornithologists have this year received in July the Heft bearing the date 'Juli, 1891.' *Gott sei dank.* The articles published in the present year appear also to be of a higher class than many of those formerly issued in the *Journal*, and some very important papers by Dr. Reichenow, Dr. A. B. Meyer, Herren Schalow, Hartert, &c., have been published. The chief interest centres round the collections which that greatest of modern naturalist-explorers, Emin Pacha, has sent to Berlin; and the birds obtained by him during his journey from Bagamoyo to Lake Tanganyika are fully described by Dr. Reichenow. The novelties are not many, but are sufficient to show that there is much to be done in German East Africa before our knowledge of its ornithology approaches completion. English naturalists will await with eagerness the zoological work of our Consul in Mozambique, Mr. H. H. Johnston, C.B., for the whole of the district in his sphere of influence is practically unexplored as far as natural history is concerned, and at present our knowledge is almost a blank. To Mr. Johnston and his companions, therefore, English zoologists are now looking for information which shall connect the work of Böhm and Emin with that of Kirk and Livingstone.

IN a recent paper to the Société des Ingénieurs Civils, M. Haubtmann states that in London the cost of the electric "horse hour" is 0·375 francs, that is three times the cost of gas. In Paris it is 0·90 francs, and at Saint Brieuc, the town where, since June 1 last, it is cheapest in France, it is still 0·52 francs. At Fribourg it has the lowest cost in Europe, 0·15 francs, and 0·10 francs for a consumption over 20 horse-power. Such differences, he points out, do not arise from difference in cost of motor force, for, deducting that, the horse-hour still remains in Paris at 0·75 francs, while in Fribourg it is 0·125 francs. They arise from differences in the amounts of capital engaged, and in the systems adopted.

IT is stated that a memorial is about to be presented to the United States Congress asking for the creation of a Government Department of Public Health, with a Cabinet officer at its head, to be known as the Medical Secretary of Public Health.

THE Danish Academy of Sciences has recently offered the following among other prizes:—A gold medal, worth about £17, for an exposition of the theory of electric vibrations in limited and resting bodies in general, with a special application to simple forms of perfect conductors, so that for these cases, the mathematical problem may be explained, and if possible solved. A prize of about £22, for an investigation showing in the case

Digitized by Google

of our four principal cereals, the nature, and as far as possible the proportional quantities, of the chief carbohydrates found at different stages of ripeness. Memoirs to be accompanied with preparations. A prize of about £27 for a complete account, accompanied with preparations, of the *Phytoptocidia* found in Denmark, and a monographic exposition of the species of the genus *Phytoptus* (in its old and wider sense), which inhabit the various galls, found on a particular plant, with the view especially of showing whether several usually different galls of the same plant species arise from the same *Phytoptus* in different phases of its development. In choosing a plant, preference should be given for one in which these galls have an economic value, as is the case, *e.g.*, with some occurring on the beech. Further, the Academy desires an exposition, as complete as possible, of the development of a particular species of *Phytoptus*. The date for the first is October 31, 1892; for the two others October 31, 1893. Memoirs may be written in Danish, Swedish, English, German, French, or Latin.

THE fürstlich Jablonowsky Gesellschaft, recognizing the fact that the determinations of the secular perturbations of the orbits of the interior planets, in the form in which they have been left by Le Verrier, are not satisfactory, and that probably the anomaly in the motion of the perihelion of Mercury is to be explained by the fact that the differential equations have been treated linearally, offers a prize of 1000 marks for a new determination of the secular perturbations of the orbits of Mercury, Venus, the Earth, and Mars, in which the terms of a higher order are taken into account. Competitors are to send in the results of their investigations before November 1894, observing the usual rules to secure the anonymity of their papers.

THE *Educational Times* states that the Supreme Council of Hygiene of Austria has been engaged in discussing the advantages of erect as compared with slanting writing, and the official Report of Drs. von Reuss and Lorenz points strongly in favour of the former. They point out that the direction of the written characters has a marked influence on the position of the body. In "straight" writing the scholar faces his work, and is spared the twist of the body and neck, which is always observable in those who write slantwise, and one common cause of spinal curvature is thus obviated. The erect method is, therefore, expressly recommended for use in schools, in preference to the ordinary sloping lines.

WE have received the eighteenth Annual Report of the Geological and Natural History Survey of Minnesota. It consists of a summary statement for 1889, report of field observations made in 188 and 1889, by N. H. Winchell; American opinion on the older rocks, by A. Winchell; additions to the library of the Survey since 1884, and a list of publications of the Survey.

L'Électricité points out that the new electric photophone, which consists of a small glow lamp at the end of an elastic tube used for throwing a strong light for surgical purposes into the mouth, ear, &c., was really suggested by the action of the water jet in the luminous fountains now so common, and that these really owe their origin to a laboratory experiment by M. Becquerel in 1876.

HERR KLENZE, we learn from a German source, has been making inquiry into the digestibility of different kinds of cheese. The most easily digested, he found, were Cheshire and Roquefort; while others are ranked as follows, in ascending order of difficult digestion: Emmenthal, Gorgonzola, Neuchâtel, Ramadour, Rotenburg, Mainz, fromage de Brie, and (most indigestible of all) Swiss cheese.

IN recent numbers of the *American Journal of Science* (February 1891) and *Ciel et Terre* (July 1 and 16, 1891) attention is drawn to the remarkable conclusions arrived at by Dr. Brückner in his work entitled "Klimaschwankungen"—the most complete work extant upon the question of the variation of climate—in which he shows that the climate has not undergone any continuous variation from the earliest historic time, but that it oscillates, and presents alternately periods of heat and cold, and of dryness and humidity, the period being about 35 years, which, it will be observed, is a multiple of the period of frequency of sun-spots (11 to 12 years). M. Penck, the eminent German geographer, has drawn some interesting conclusions as to the probable effects upon the harvests of the world.

PART 34 of Cassell's "New Popular Educator" has just been issued, and contains articles on applied mechanics, algebra, botany, electricity, and comparative anatomy.

MR. G. C. HOFFMANN, of the Geological and Natural History Survey of Canada, has made a microscopical and chemical examination of a peculiar form of metallic iron found on St. Joseph Island, Lake Huron. It appeared in the form of spherules disseminated through a thin deposit of dark reddish-brown limonite which coated certain faces of some surface specimens of quartz. These metallic-looking spherules were found to consist of nuclei of silicon coated with a humus-like substance, which in turn was overlain by a metallic layer containing all the elements most frequently met with in meteoric iron. But the small proportion of nickel present (0·11 per cent.), and the relatively large amount of phosphorus (1·07 per cent.), as also the fact that the spherules contain nuclei apparently of a concrete character, leads Mr. Hoffmann to suggest the possibility of a terrestrial source for the material, upon the assumption that it has resulted from the reduction of an iron-salt by organic matter. The paper, which is accompanied by four coloured plates, appears in the Transactions of the Royal Society of Canada, 1890.

THE preliminary results of some investigations upon the growth of the face are stated by Prof. G. M. West in *Science* for July 3. The values obtained in the case of measurements of the female face point to the existence of three distinct periods of growth, the first ending at about the seventh year, and the third beginning at about the age of fifteen. The abrupt transition from one period to the next is indicated by the very slow growth of some children until the ages of eight or fourteen, when a rapid development often occurs. From the fifth to the tenth year the average growth appears to be about 6·5 mm. During the next four years it is 6·2 mm., and from this time little advance is made, the maximum of 128 mm. being reached at about the age of twenty. The male face is larger than the female face at all ages. Its growth is also more rapid, and continues later in life. The measurements have been on 2500 persons, including both sexes.

PROF. TITO MARTINI, of Venice, contributes to the issue of the *Rivista Scientifico-Industriale* for the end of June, the results of some experiments on the crystallization of thin liquid films. He finds that a strong solution of sodium sulphate, when cooled to near its saturation point, possesses a viscous character which enables it to form a thin film on a metallic ring, as in Mr. Boys's experiments with soap-bubbles. On rapid evaporation such a film crystallizes to an extremely beautiful open lattice-work of minute crystals, which preserve their transparency for some time, and then effloresce and crumble to powder. The experiments succeeded with rings up to thirty-six millimetres diameter. Similar experiments with ammonium chloride and sodium hyposulphite have hitherto proved unsuccessful. With a transparent film of liquid sulphur, however, even more beautiful results have been obtained. The author regards such experiments, besides being eminently suitable for lecture demonstration, as likely to throw light on the nature of molecular arrangement in relation to crystallization.

Digitized by Google

THE same number of the *Rivista* summarizes a somewhat important communication to the Naples Royal Academy of Physical and Mathematical Sciences, in which Prof. Dino Padelletti urges that the usual investigation for the movement of the plane of oscillation of Foucault's pendulum in relation to the earth's rotation is insufficient. The author contends that the problem for latitudes between the pole and equator is more difficult than would appear from the usual simple solution, and cannot be solved by the principle of inertia. He proposes an equation derived from the principle of composition of the rotational forces.

A METEOROLOGICAL journal in the Russian language, the *Meteorologitscheskij Westnik* (Messenger), has lately appeared under the competent editorship of Woeikof, Rykatschew, and Spindler; its general plan seems to be like that of the German *Zeitschrift*. The idea of starting it arose at a meeting of the Russian Naturalists and Physicians at St. Petersburg in the end of 1889. Four graphic tables are given in this journal, showing the course of the meteorological elements during 1889 at the agricultural experimental station of Sapolje, also measurements of ground temperature, &c.

THE *Selborne Society's Magazine* for July contains the first of a series of articles on the Kew Museums by Mr. J. R. Jackson; others on the effects of environment on plants, and other interesting matter. Among the correspondence are complaints from Warwickshire that the Wild Birds Preservation Act is a dead letter there, as the "authorities," whoever they may be, take no trouble in the matter. On the other hand, the inhabitants of Shetland are fully alive to it.

THE last volume (xxii., 6) of the *Trudy* of the Society of Naturalists of Kazan contains the second part of Mr. Korzchinsky's valuable researches into the northern limits of the black-earth steppe region of East Russia. In the first part-published in 1888, the author gave the results of his explorations in the province of Kazan. He now confirms his conclusions by further exploration in Samara, Simbirsk, Perm, and Ufa. He gives the northern limits of the black-earth steppe vegetation, and shows that they depend neither upon climate nor upon the altitudes, but chiefly upon the courses of the rivers.

ACCORDING to *La Nature*, the telephonic service of Paris, rapidly developing of late, will soon include an immense central telephonic office in the Rue Gutenberg, capable of serving directly 30,000 subscribers, without connection with the other offices of the quarter. The work is being actively pushed forward. Cables are being laid in the sewers, an enlargement of which, at certain points, is rendered necessary. There were 7800 subscribers in Paris last October. Paris has now telephonic communication with Brussels, Marseilles, Lyons (which also communicates with Marseilles), Lille, Havre, Rouen, and London. Twenty-eight towns in France have a telephonic system. There are two in Algeria, in Algiers and Oran. Lille and Roubaix, Lille and Dunkirk are connected by telephone; and, ere long, connection will be formed between Lille, Valenciennes, Calais, and Fourmies, between Lyons and Saint Etienne, between Dieppe and Rouen, between Marseilles and Nice.

THE climate of the Greek island Cephalonia has been lately described by Dr. Partsch (*Petermann's Mitt.*). We note the following features. At Argostoli temperature reaches a maximum in July (23°·3 C.), whereas in Corfu and Patras it does so in August. With several days' calm and bright sunshine, in the bay, the air, laden with moisture, becomes unbearably hot and close. Yet the natives go but little to the wooded hills behind, where the temperature goes down sometimes to 15°·5 C. or lower. Mules bring down snow nightly, in summer, from covered pits in the hills, for supply of restaurants, &c. As to rain, there is a sharp contrast between the wet winter-half and the dry summer-half of the year. The annual rainfall (3½ years) was about 35 inches. The autumn rains are ushered in by severe thunderstorms. November and December are the wettest months, but about Christmas there is usually a short time of fine weather. March is extremely variable, and often very cold. With May begin the rainless months, and the drought is sometimes considerably over 100 days. Five months have sometimes passed with but a few slight showers. On this greatly depends the currant cultivation: a brief downpour may spoil the crop. Snow falls seldom in Argostoli, but often on the hills. Dew is plentiful in summer, but its salt precipitate is feared. Wind is greatest in winter, southerly winds prevailing, especially south-east. A hot south wind (the *lambaditta*) blows, rarely, in early summer, and with evil effects to vegetation. The fresh north-west wind (*maestro*) brings cumulus clouds on the hills.

MR. F. HOWARD COLLINS, the author of a useful epitome of Mr. Herbert Spencer's system of philosophy, has written a pamphlet in which he discusses the causes of the diminution of the jaw in the civilized races. In opposition to the views of Weismann, he contends that the phenomenon is due to "disuse"; and the argument, as he presents it, deserves to be seriously considered. Some time ago Mr. Collins sent to NATURE a letter in which he gave some account of the ideas which he now expounds more fully. In the preface to his pamphlet he seems to imply that the letter was not inserted because, according to a belief said to be current among certain biologists, the editor of NATURE is "more willing to publish letters contending that acquired faculties are not inherited than those contending that they are." Mr. Collins has too readily allowed himself to be influenced by the belief of "certain biologists." If he supposes that it is possible for the editor of NATURE to print all the letters sent to the paper for publication, he must have a very inadequate conception of an editor's functions.

To throw light on some physiological processes, Herr Hofmeister recently experimented (*Archiv für experim. Pathol.*) on the swelling of plates of gelatine in various solutions; the plates being taken out from time to time, dried, and weighed. With salt solutions of various concentration, the gain of weight was large in the first days, then gradually fell off, as in former experiments with pure water. The effect varied with the nature of the salt; and even with solutions holding the same number of molecules in 1000 parts water, the swelling varied as much as five-fold. This difference, it is pointed out, is related to attraction of the salt for water; the greater the attraction, the more difficult the entrance of water into the plate. But that this is not the only factor is proved by the swelling in pure water being always much less than that in the solutions. Experimenting with ordinary salt, the gain of weight proved to consist both of water and salt, both dependent (but differently) on concentration. With increase of the latter, the gain of water rises to a maximum (about 13 per cent.), then declines; but the gain of salt goes on always increasing proportionally to the concentration. The remarkable property salts have of increasing the gain of water beyond what occurs in pure water is also shown by indifferent organic substances, as cane-sugar and alcohol. Experiments were further made on swelling of gelatine plates in methyl-violet solutions, and with the result that the concentration of the solution in the plates was always much greater (over 30 times) than that in the solution presented. The colouring-matter is taken up in relatively much greater quantity than the water. Further, gelatine takes up somewhat more colouring-matter relatively from a dilute than from a concentrated solution. The forces concerned in these phenomena, and

Digitized by Google

which are neither purely mechanical nor chemical, Herr Hofmeister brings into analogy with those occurring in absorption of gases by liquids, the reciprocal solution of liquids, adsorption of gases on solid bodies, &c.

THE *Photographic News* quotes the following from the *Scientific American*, December 9, 1848:—"*New Electrical Light.*—The inventors of a new electrical light, exhibited at the Western Literary Institution, Leicester Square, London, on its recent reopening under the new auspices, expect, it is said, to apply it generally to shop and street illumination, and they state that, while the conveying will cost no more than gas, the expense of illumination will be one-twelfth the price of the latter light. The current of electricity, in passing through the two pieces of charcoal which form the poles of the circuit, and are excluded from all access of air, gives, in this case, it is said, an intense and beautiful white light, with the effect of daylight, to a much greater extent than the lime does, and having this advantage, that it is sustained and continuous. If Messrs. Staite and Petrie can thus produce a steady and sustained light they have accomplished what has hitherto been the sole preventive to the substitution of galvanism for gas. The *Mechanics' Magazine* states that this one light completely eclipsed ten gas lights and an oxyhydrogen. The gas companies had better look out. The dissatisfaction of the public with their mismanagement may have begotten a rival destined to eclipse many more than merely ten of their gas lights."

WITH the view of certifying to the efficiency of teachers of public elementary schools to give instruction in woodwork in accordance with the provisions of the Code (1890), the City and Guilds of London Institute is prepared to issue certificates to qualified teachers of public elementary schools on the following conditions:—The candidates will be required to give evidence of having regularly attended during each of two sessions, a course of at least twenty practical wood-working lessons in a school or class certified by, and under an instructor approved by, the Institute. The candidates will further be required to pass an examination at the end of each year's course, to be conducted by examiners appointed by the Institute, and to pay a fee of five shillings for each examination. For the first year, candidates who have attended an advanced course of instruction will be exceptionally admitted to the second year's examination without having passed the first, and will be eligible for the teacher's certificate. The examination fee for such candidates will be ten shillings. The written examination will include questions founded on such subjects as the following:—*Woods.*—Places from which some of the commoner woods are obtained. Their characteristic properties and uses. The general structure of cone-bearing and leafy timber trees. The meaning of seasoning timber. Effects of shrinkage and warping. Identification of specimens of wood. The questions will be limited to oak, ash, elm, beech, mahogany, sycamore, basswood, white deal (spruce), red pine (Scotch fir), yellow pine.

Das Wetter for July reports a curious case of globular lightning which occurred at Berga, near Schlieben, in Germany, between 3 and 4 o'clock on the morning of July 1. The lightning entered the chimney and split into two parts, one portion ran along the rafters of the roof, and the other entered a bed-room occupied by a man with his wife and three children. The man, who was up, on account of the violence of the storm, saw the ball jump on to the bedstead, which it broke, and from there it slowly travelled to the opposite side of the room, and disappeared, with a loud crash, through the wall. None of the occupants were injured, further than being deafened for a short time.

THE additions to the Zoological Society's Gardens during the past week include a Banded Ichneumon (*Herpestes fasciatus*) from West Africa, presented by Dr. Arthur Williams; a Black Stork (*Ciconia nigra*), European, presented by Lord Lilford, F.Z.S.; two Nilotic Crocodiles (*Crocodilus vulgaris*) from Africa, presented by Dr. Lester; two Black Storks (*Ciconia nigra*), European, two King Parrakeets (*Aprosmictus scapulatus*) from New South Wales, purchased; a Laughing Kingfisher (*Dacelo gigantea*) from Australia, deposited.

OUR ASTRONOMICAL COLUMN.

RESEARCHES ON THE MEAN DENSITY OF THE EARTH.—The *Monthly Notices of the Royal Astronomical Society* for June contain a brief account by Prof. A. Cornu of the experiments M. Baille and himself have been making for some years to determine the mean density of the earth. The apparatus employed is fundamentally the same as that used by Cavendish. It consists of a horizontal aluminium rod, suspended by a torsion thread 4 metres long, carrying at each end a ball of copper, bismuth, iron, or platinum, and at its centre a vertical mirror reflecting the divisions on a millimetre-scale 5 metres away. Two globes of mercury are used to produce the torsion couple. The displacements of the scale-divisions are observed with a telescope, and indicate the angular displacements of the rod. The chief improvements which have been made upon the apparatus used by Cavendish, Baily, and Reich, are as follows:—(1) The length of rod connecting the suspended balls has been reduced to 0·50 metre, *i.e.* to a quarter the length adopted by the above-named observers. (2) The attracting masses have been reduced to 10 kilogrammes. Cavendish used masses weighing more than 140 pounds. And the method of using fixed globes which can be quickly filled with mercury has been advantageously substituted for the movable lead weights. (3) The complete oscillation of the balance arm is registered on a chronograph by observing and recording the transits of the reflected scale divisions. (4) The use of an annealed glass fibre to eliminate errors due to displacements of the zero point. (5) The screening from variations of electric potential by putting all parts of the apparatus in metallic connection with the earth. (6) The copper case protecting the balance arm is a good conductor of heat, and of sufficient thickness to eliminate the disturbances due to variations in temperature. The authors hope soon to obtain an estimation of the probable error of their measures, and to arrive at a definite result for the constant they are determining.

PARALLAX OF P URSÆ MAJORIS.—Vol. xxxviii. of the "Astronomical Observations of the University Observatory of Königsberg" contains the heliometer observations of P Ursæ Majoris (Arg.-Oeltzen 11677) made by Dr. Julius Franz, from which he deduces the parallax $0''\cdot1002 \pm 0''\cdot0065$, or approximately $0''\cdot10 \pm 0''\cdot01$.

THE PROGRESS OF MEDICINE.

THE Bournemouth meeting of the British Medical Association has been a great success, and a great deal of useful work and discussion has been recorded. Among the addresses we may refer to the President's (Dr. J. R. Thomson), on the present position of medical officers of health; of Dr. Lauder Brunton, on twenty-five years of medical progress; of Dr. J. Chiene, on rest as a therapeutic agent in surgery; and others on lunacy legislation, the uses and prospects of pathology, &c.

We make the following extracts from Dr. Brunton's address, which presents us with a most admirable and masterly analysis of recent progress:—

. . . Perhaps there is no period in the whole history of medicine in which such rapid changes have taken place as in the last five-and-twenty years. It is impossible to give anything like a complete account of these in the brief space of one hour, and I shall therefore restrict myself to a few of the more prominent points, and especially those that have come directly under my personal cognizance; for, like the man who made one-half of his fortune by attending to his own affairs and the other half by leaving other people's alone, I may probably utilize the time at my disposal best by speaking of what I know myself and leaving other things out.

Advances in Knowledge and Teaching due to Experimental Method.—These changes have occurred both in the profession

Digitized by Google

itself and also to some extent—in this country at least—in the education and training of the men who enter it. We notice, first, that a very great increase has occurred in the knowledge of the nature, causation, and treatment of diseases possessed by the profession as a whole, but perhaps a still greater gain is the general adoption of the experimental method by which most of our recent knowledge has been acquired, and from which we may hope for even greater advantages in the future. In correspondence with the acquirement of knowledge, we notice also a great alteration in the teaching of medicine, and especially prominent is the tendency to make such teaching practical instead of theoretical by training men to place their dependence upon objective facts, and not to receive without experimental data the theories or speculations of any master, however great he may be. . . .

Direction of Advance.—The greatest advance made in the last twenty-five years has been in the direction of the accumulation, co-ordination, and teaching of facts instead of theories, of the phenomena of Nature as opposed to the fancies of the human mind.

Co-ordination of Facts.—But the mere accumulation of facts is of little use unless they can be so arranged, compared, and grouped as to bring them into relationship with some general law, and this we find in the world's history has been done from time to time by some master-mind. . . .

Influence of Darwin.—Medicine, both in its principles and practice, is really a subdivision of biology, and this, like all other branches of knowledge, has been most profoundly modified by the general acceptance of Darwin's great thoughts—the doctrine of evolution, the struggle for existence, and the survival of the fittest. Wherever we turn we find that Darwin's influence has modified the direction of thought, and whether the study concerns the evolution of the elements, the evolution of the planetary systems, of living beings, of communities, of customs, of laws, of literature, science, or art, in every department of human knowledge we find that men, consciously or unconsciously, are influenced by Darwin's work. It is with shame I confess that five-and-twenty years ago, although I had taken a University degree not only in medicine but in science, and might therefore be supposed to be acquainted with his work, I did not even know of the existence of his "Origin of Species," and I first heard its name in Vienna from the lips of an Austrian who was speaking of it in terms of the highest praise. "What is it?" I asked, and my question then seemed to cause my foreign friend as much astonishment as it causes myself now, when the possibility of such ignorance seems to me, as it must to you, almost incredible, and yet such was the fact. The publication of Darwin's "Origin of Species," in 1859, has done more to change the current of human thought than anything else for centuries, but while its influence is everywhere felt, biology and all its subdivisions have been more especially affected.

Changes in Medical Students.—But great as the changes have been during the last five-and-twenty years in the profession itself, they are perhaps quite as great in the men who enter it. . . .

Long ago the doctor's means of diagnosis consisted in inspecting the tongue, feeling the skin, counting the pulse, shaking the urine, and looking at the motions and the sputum. But now, in addition to a thorough training in auscultation and percussion, students have to learn the use of the laryngoscope, ophthalmoscope, and otoscope, and the application of electricity. They have to acquire a knowledge of the chemistry of the urine and its alterations in disease, and, what takes still more time, they have to learn the microscopical appearances, not only of the tissues and excretions in health, but their alterations in disease, and must be acquainted with the methods of staining so as to detect tubercle bacilli and other disease germs. . . .

Departments of Greatest Advance.—Five-and-twenty years ago we knew only too well that typhus was infectious, and that pyæmia and erysipelas were likely to spread in a ward when once they got into it, but we did not know then the causes of these diseases as we do now, nor had we the same means at our disposal wherewith to combat them. The departments in which the greatest advances have been made within the last five-and-twenty years are in those of fevers and diseases of the nervous system. A new era in the study of the latter was foreshadowed by the experiments of Fritsch and Hitzig on the brain of the dog, but it can only be said to have fairly begun with Ferrier's localization of the cortical centres, both motor and sensory, in the brain of monkeys. For the brain of the dog was too unlike that of man for experiments upon it to be of much practical use in the diagnosis of human ailments, while the likeness in the brain of the monkey to that of man at once allowed conclusions drawn from the experiments upon the former to be transferred upon the latter. Yet if we try to describe in one word the department in which medicine has made the greatest progress within the last quarter of a century, that word must be "fevers"; for during this time we have learned to recognize fever by the use of the thermometer in a way we never did before; we have learned the dependence of the febrile process in the great majority of cases upon the presence of microbes in the organism, and we have become acquainted with an immense number of chemical substances which have the power both to destroy the microbes and to regulate the febrile process.

Introduction of the Thermometer.—It is true that the thermometer was used by Danielssen, in leprosy, before the year 1848, and its more general use began with Wunderlich's observations nearly thirty years ago, but it is only within the last five-and-twenty years that its use has become at all general. . . .

Nature of Fever.—The thermometer has not only enabled us to detect the onset and to watch the progress of fever, but in conjunction with microscopical research, physiological experiment, and chemical analysis it has enabled us to gain a fuller knowledge of the nature of the febrile process itself. We know that during it the organism is consuming rapidly, or, as Dr. Donald MacAlister graphically says, it is like "a candle burning at both ends," and we have learned scientifically the reasons for the practical treatment, of which Graves was so proud that he wrote as his own epitaph, "He fed fevers." We have learned also, to a great extent, the necessity for the elimination of the waste products, or ashes as we may term them, which the excessive combustion produces, and thus we know why the surgeon is so anxious regarding the result of an operation when the kidneys of his patient are inadequate. For if any febrile attack following the operation should lead to increased demands upon these secreting powers, they might fail to meet it, and the retained excreta would poison the patient.

New Methods.—The rapid increase in our knowledge has been due not merely to the constant use of old methods, but to the introduction of new ones, and more especially to the general recognition of the fact that the same strategy which has often proved so successful in war is to be applied in attacking complex problems. They are to be separated as far as possible into their several components, and each of these is to be overcome in detail. As presented to us by observation at the bedside, the problems of disease are too complex for us to solve, and we are only succeeding in doing it by examining the various factors one by one in the laboratory. The greatly increased powers of the microscope and the better methods of illumination have been of the greatest service, but their utility would be very much less than it is had it not been for the general introduction of the microtome and the invention of new methods of staining. When I was a student the microtome was only used for cutting sections of wood in the class of practical botany. About that time it was employed by Mr. Stirling, Prof. Goodsir's assistant, in the preparation of animal tissues, but I believe that we owe its general introduction to Prof. Rutherford. The facility with which sections are made by it has made microscopical research much less tedious, and has enabled trained histologists to do more work in a given time, and medical students to acquire knowledge more rapidly. But without the method of staining introduced by Weigert and Ehrlich, we should, even with the best microscopes, be unable to recognize most of the microbes which are so important in the causation of disease.

Good Out of Evil.—It is very interesting to see how good may come out of evil, and a striking illustration of this is afforded by the history of medicine in the period we are now considering. For it seems to me that we can trace a great part of our knowledge of disease germs and of the antiseptic remedies we use in treatment to the cupidity and stupidity of the Spaniards of the Cordilleras. Their cupidity led them to cut down the cinchona trees of the Andes in order to fill their pockets with the gold they received in exchange for the precious bark, while their stupidity prevented them from planting new trees to replace those which they felled. The consequence of this was that quinine became so dear that it was evident that anyone who could produce it artificially

Digitized by Google

would make his fortune. Amongst others, Perkins tried to do this, and, although he failed, yet in the attempt he discovered the anilin dyes, whose staining powers have not only helped us so much in ordinary histological research, but have made it possible to distinguish disease germs which without them would have been invisible. But the discovery of the anilin colours was only one outcome of the attempt to make quinine synthetically, for the impulse which it gave to the study of aromatic compounds has led to the production of salicylic acid and acetanilide, antipyrin, phenacetin, and all the other antipyretic remedies whose number is probably legion, and whose names already have become so numerous as to be troublesome. Here we see good has arisen out of evil; for if the price of quinine had not been so high, the researches which have proved so useful might not have been begun even yet.

Small and Great, Foolish and Wise.—In looking at another of the greatest advances which medicine has made—namely, the knowledge of infective disease—we can see how enormous results can arise out of very small beginnings, and the safety of nations may be consequent upon a research which many men would have termed useless or even frivolous. I can hardly fancy any better illustration of St. Paul's observation about the foolish things of this world confounding the wise than Pasteur's researches on tartaric acid; for what could seem more foolish to the so-called practical man than the question, "Why does a crystal of tartaric acid sometimes take one shape and sometimes another?" Yet from an attempt to answer this question has arisen the whole of Pasteur's work on fermentation in general, and on that of wine, beer, and vinegar in particular, whereby he has been able to save millions to his country by accelerating the production of vinegar and preventing the souring of wine and beer. His observation that tartaric acid sometimes turned the ray of polarization to the right, sometimes to the left; that, indeed, there were two crystals apparently alike, but really different; and that these could be combined so as to form a symmetrical crystal having no power of rotation, led him to look to life and living beings as the source of asymmetry. He tried to produce this asymmetry in salts of tartaric acid by fermentation, and found that during the process an organism developed which eats up the dextro-tartaric acid, and leaves the lævo-tartaric acid behind. This led him to investigate such minute organisms, and, by simplifying the soil in which they grew, and separating the organisms one from another, he learned the conditions of their growth, and showed that most processes of fermentation were due to the presence of living organisms. It is true that while Pasteur was still a boy at school, Peyen and Persoz had shown that the liquefaction of starch and its conversion into sugar was due to diastase, and that Dumas in a report on a paper by Guérin-Varry had pointed out that, although unlike diastase, the active principle of the gastric juice had not been isolated, it was probably a ferment of a somewhat similar kind. Dumas classed yeast as a ferment along with diastase, and the fact that such a process as conversion of starch into sugar could be effected without a living organism naturally rendered it all the more difficult for Pasteur to prove his thesis that most fermentations were due to living organisms.

Chemical and Biological Views of Fermentation.—The two views of the action of ferments—namely, the chemical and the biological—may, I think, fitly be likened to Pasteur's two kinds of tartaric acid, each by itself being lopsided and incomplete, forming a symmetrical whole only when united. There can be no doubt of the truth of the chemical view that diastase is not a living organism, and yet converts starch into sugar. There can be as little doubt of the biological view that yeast and other organisms which cause fermentation are living bodies, and that without the presence of these living bodies alcoholic, acetic, and other forms of fermentation would not exist.

Microbes and Ensymes.—But recently we have come to recognize that these living organisms may produce their effect by manufacturing chemical ferments, and that these ferments may occasionally do the work, although the organisms which form them may be absent. It is quite true that it is difficult—perhaps impossible—to get fermentation from the dead yeast plant, but we may find a parallel for this in the fact that the pancreas of the higher animals sometimes yields an active ferment and sometimes not. Nor need we wonder that the ferments produced by microbes have but a slight action compared with those of the microbes themselves, if we remember how very little power of digestion a dead pig's stomach has as compared with the amount which can be digested not by the live animal itself only, but by the herds of swine consisting of its "fathers and mothers, its brothers and sisters, its cousins and its aunts," during all the term of their natural lives; for in the process of fermentation microbes are growing, fermenting, and dying with great rapidity, and many generations occur in a fermenting fluid in the space of a few hours, so that the total effect they produce will be out of all proportion to any which can be got from the microbes themselves at a single instant.

Microbes and Disease.—From organisms as a cause of fermentation and of the diseases of wine and beer, Pasteur went on to investigate their action as causes of disease in living beings—first in the silkworm, next in the lower animals, and, lastly, in man. He established the dependence of the silkworm disease and of anthrax upon the presence of specific microbes which could be transmitted and communicate the disease, and by destroying the infected eggs of the silkworm he eradicated the disease and restored the silk industry to France.

Weakening of Disease Germs.—But while this investigation is interesting to us as illustrating the probable cause of the disappearance of typhus fever, to which I have already alluded, Pasteur's researches on anthrax are still more important as bearing upon the question of protective inoculation; for he found that the disease germ could be cultivated outside the living body and grown in flasks under varying conditions, some of which were favourable and others unfavourable to its growth. High temperature enfeebled the virus, so that it no longer killed an animal with the same certainty, and by inoculating first with a weak virus and then with one successively stronger and stronger, he found that animals could be completely protected either from inoculation by the strongest virus or by infection from other animals suffering from the actual disease.

Increase in Virulence of Disease Germs.—Another extraordinary fact which he made out was that the virus thus weakened, so that it will not kill a guinea-pig a year old, and still less a sheep or ox, may again be rendered most potent by inoculating a feeble animal, such as a guinea-pig a day or two old, from this older and stronger guinea-pig's, the strength of the disease germs increasing with every inoculation, until finally sheep and cows may be killed by it. We can thus see how an epidemic of disease beginning sporadically, and attacking weak individuals, may gradually acquire such strength as to attack and carry off the strongest.

Pure Cultures.—Pasteur's plan of growing disease germs outside the body in broth, although of the utmost value, did not allow a convenient separation of different germs; but this can now readily be done by Koch's plan of sowing them, not in a liquid medium, but on solid gelatine spread on glass plates, so that the growth of the germs can be daily watched under the microscope, and inoculations made from single colonies on other plates until pure cultures have been obtained. By thus isolating the different microbes, we learn their life-history, the mode in which their growth is influenced by differences of soil, of temperature, of moisture, by the addition of various substances which either favour or retard their growth, and, last but not least, the effect which one microbe has upon another when they are grown together at the same time.

Struggle for Existence amongst Microbes.—For even amongst these minute organisms the struggle for existence and the survival of the fittest exists, like that which Darwin pointed out so clearly in the case of higher plants and animals. . . .

Struggle for Existence between Microbes and the Organism.—But it is not merely between different species of microbes or different cells in an organism that this struggle occurs. It takes place also between the disease germs and the cells of the organism which they invade, and the result of the struggle may be determined, not by some powerful agency which weakens or destroys either the organism or the microbe, but by some little thing which simply inclines the scale in favour of one or the other. Thus, in the potato disease, the victory of the invading microbe and the destruction of the potato, or the death of the microbe and the health of the tuber, may depend upon some condition of moisture or possibly of electrical change in the atmosphere which aids the growth of the microbe disproportionately to that of the potato. These atmospheric conditions need not necessarily be antagonistic to the potato, they may even in themselves be advantageous to it; but if they help the microbe more than the plant, the microbe will gain the victory and the plant be destroyed.

Fight between Cells in Higher Organisms.—The fight between

Digitized by Google

the organs which Æsop describes in his fables actually occurs between the cells in some vertebrate animals, and the schism predicted by St. Paul as the result of such a fight actually takes place. For in the tadpole, at one stage of its existence some of the cells at the base of the tail begin to eat up others, with the result that schism occurs and the tail falls off.

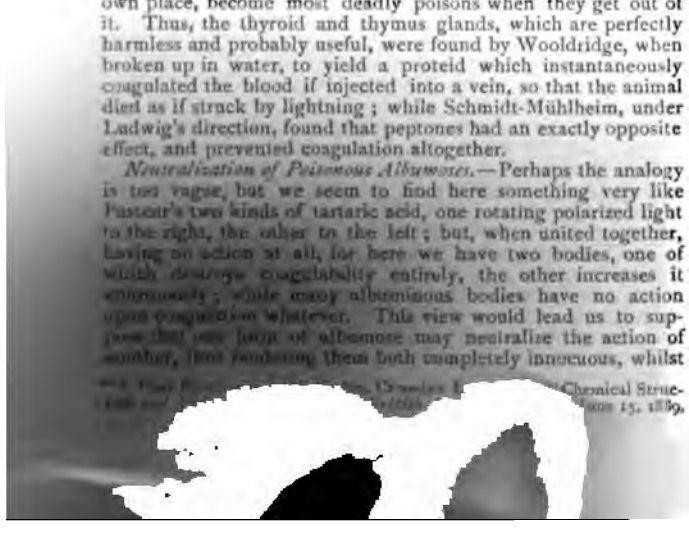
Phagocytosis.—This struggle for existence between the cells of an organism and microbes has been beautifully shown by Metschnikoff in the Daphne or water flea, where the process of the cells eating up the microbes or the microbes destroying the cells can be actually observed under the microscope. This process of phagocytosis is now regarded by many as only a small part of the struggle between an organism and a microbe, but it is impossible to see one part of a microbe half digested by the cell in which it is embedded, while the part outside remains unaltered, without believing that the process is one of great importance. At the same time, it seems that the process of phagocytosis, where the microbe and the cells meet in close conflict, bears about the same relationship to the total struggle that a bayonet charge bears to a modern battle. The main part of the fight is really carried on at some distance by deadly weapons—by bullets in the case of the soldier, and by ferments, poisonous albumoses, and alkaloids on the part of the cells and the microbes. In some of Metschnikoff's observations we can almost see this process, for he has figured leucocytes dead, and apparently burst by the action of conidia, lying close to but yet outside them, as if these conidia, like the dragons of fable, had spit out some venom which had destroyed them.

Venom of Microbes.—Within the last few years attention has been gradually becoming directed less to microscopical examination of the microbes themselves and more to chemical investigation of the ferments and poisons which they produce; yet, strangely enough, the very moment when chemistry is becoming more important than ever has been chosen to minimize the teaching of it in medical schools, and examination in it by licensing bodies. It is now possible to separate the albumoses and poisons from the microbes which produce them either by filtration, or by destroying the microbes by graduated heat; for, as a rule, they are destroyed by a lower temperature than the albumose or poisons which they form.

Microbes and Enzymes.—As the albumoses produced by microbes are nearly allied, chemically and physiologically, to those formed in the alimentary canal of the higher animals by digestive ferments, it is natural to suppose that microbes, like the higher animals, split up proteids, starches, and sugars by enzymes, which they secrete, and which in both cases may be obtained apart from the living organisms which produce them; that, in fact, we should be able to isolate from microbes bodies which correspond to pepsin or trypsin, just as we can isolate these from the stomach or pancreas of an animal. In some, although not in all cases, this attempt has succeeded.[1]

Poisonous Albumoses.—The albumoses produced by microbes resemble those formed during normal digestion in being poisonous when injected directly into the circulation, although they may not be so greatly absorbed from the intestinal canal. One of the most remarkable discoveries in regard to albuminous bodies is the fact that some of them which are perfectly innocuous, and, indeed, probably advantageous to the organism in their own place, become most deadly poisons when they get out of it. Thus, the thyroid and thymus glands, which are perfectly harmless and probably useful, were found by Wooldridge, when broken up in water, to yield a proteid which instantaneously coagulated the blood if injected into a vein, so that the animal died as if struck by lightning; while Schmidt-Mühlheim, under Ludwig's direction, found that peptones had an exactly opposite effect, and prevented coagulation altogether.

Neutralisation of Poisonous Albumoses.—Perhaps the analogy is too vague, but we seem to find here something very like Pasteur's two kinds of tartaric acid, one rotating polarized light to the right, the other to the left; but, when united together, having no action at all, for here we have two bodies, one of which destroys coagulability entirely, the other increases it enormously; while many albuminous bodies have no action upon coagulation whatever. This view would lead us to suppose that one group of albumose may neutralize the action of another, thus rendering them both completely innocuous, whilst



either one or other alone might be a deadly poison. The albumoses formed by microbes appear frequently, if not always, to have a double action, destructive and protective, on the higher animals. Pasteur's treatment of hydrophobia is based on the idea that the spinal cord of rabid animals contains a virus and its antidote—Koch's tuberculin—may be similar in this respect, and may yet, by suitable alterations, fulfil the hopes of this able and single-minded discoverer.

Zymogens and Enzymes.—Perhaps a similar process of splitting up and recombination may explain the formation and disappearance of the enzymes, such as pepsin and trypsin, by which digestion is carried on. The pancreas of a living animal will not digest albuminous bodies like fibrin, etc., the pancreas of an animal killed during full digestion will so rapidly. Yet the fasting pancreas contains the zymogen or mother substance, which yields the digestive ferment, as has Kühne has shown, by treating it first with acid and then with alkali, it becomes active. Again, to recur to the analogy of Pasteur's tartaric acid, we seem to find that the inactive and possibly symmetrical, albuminous substance of the resting pancreas is split up by this treatment after death, during the process of digestion in life, and yields the right and active pancreatic ferment. But, if this be so, what becomes of the other half which has been split off? We do not at present know, but curiously enough Lepine has also shown that while the pancreas is pouring into the digestive canal a ferment which will form sugar, it is at the same time pouring into the circulation another ferment which will destroy sugar.

Immunity.—We must be very careful in our speculations and test them by experiment, but such observations as these may tend to throw some light upon the nature of immunity. Immunity is probably a very complex condition, not altogether dependent upon any single factor, but we can easily understand that if a microbe has gained an entrance into an organism, and produces a proteid or an albumose poisonous to the organism which it enters, it may grow, thrive, and destroy that organism, while the injection of some other proteid which would neutralize the poison might save the animal while the microbe would perish.

Cure of Anthrax.—Thus Hankin has found that, while a mouse inoculated with anthrax will die within twenty-four hours, a rat resists the poison altogether; but if the rat after being inoculated with the disease has a few drops of rat's serum injected into it, instead of dying, as it would otherwise certainly do, it survives just like the rat, and from the spleen of the rat Hankin has isolated a proteid which has similar protective action to that of the serum.

Cure for Tubercle.—Working on similar lines, Berlioz and Lépine used the injection of goat's blood in phthisis to stop, if possible, the progress of tubercle, and Richet has used the serum of dog's blood, for the goat is quite immune and the dog is to a great extent, though not entirely, immune from attacks of tuberculosis. The injection of goat's blood in somewhat large quantities has been given a trial, dog's and goat's serum in small quantities of 15 to 20 c.c. at intervals of several days is still under trial.

Action of Blisters.—But if immunity can be insured by slight changes in the organism as a few drops of serum of a rat will produce in the body of a mouse, it is natural to suppose that a similar change might possibly be effected by removing the albuminous substance from one part of the body, and introducing it, perhaps after it has undergone a change, into another. As I have already mentioned, the albumoses of ordinary digestion are poisonous when directly injected into the circulation, and so are the proteid substances obtained from the thyroid and thymus glands. Why then, may not the serum of one's own blood, withdrawn by the vessels by a blister and reabsorbed again, be as good as the serum obtained from the blood of an animal?

Bleeding.—It is quite possible, too, that the good effects of bleeding may be due to a similar cause. . .

Speculation and Experiment.—The human body is a most complex piece of mechanism. We learn its action but very slowly indeed, and we are only too apt to regard the one piece which attracts attention at the moment as all important and to leave the other parts out of sight. But this is equally true of our study of the body only, for the same error manifests itself in the pursuit of knowledge of all kinds, and it is in medicine more especially that this tendency

Digitized by Google

be a matter of life or death, for upon the medical view prevailing at the moment medical practice is apt to depend, and erroneous views may lead to the death of many patients. So long as practice depends upon theories, unchecked by experiment, so long will medical practice prove fluctuating, uncertain, and dangerous. One of the greatest gains of the last five-and-twenty years is the general introduction of the experimental method, and the habit which has been growing up during it of accepting no statement unless based upon experimental data. Speculations such as those in which I have been indulging in regard to blisters and blood-letting are useful as indicating lines of experimental research, but until these have been thus tested it is foolish and may be dangerous either to accept and act upon them as true or to scout them entirely as false and absurd. Imperfect knowledge is almost sure to lead to one-sided practice, and thus, diverging further and further from the truth, ends at last in falsehood and folly.

Antisepsis.—Perhaps no better example of this can be found than antiseptic surgery, from the time of the good Samaritan down to Ambroise Paré and Sir Joseph Lister. The good Samaritan bound up the wounds of the poor traveller, pouring in oil and wine, which, only a few years ago, was recommended in an Italian journal as an excellent antiseptic. Ambroise Paré, when his ointments ran out, could not sleep for thinking of the miserable soldiers to whom they had not been applied, and was greatly astonished to find in the morning that these wretched neglected ones were better and happier than their comrades who had been treated *secundum artem*. I have no doubt that Paré's predecessors, in trying to improve upon the methods of the good Samaritan and upon the still useful friars' balsam, which is a powerful antiseptic but irritates the wound or sore, had tried to make their applications more and more irritating, not knowing that it was the antiseptic power and not the irritant qualities which were desired. Paré abolished the ointments with the irrritation they caused, and thus did great service to surgery. But a greater one yet was rendered by Lister when he recognized that the danger of operations was due to the entrance of germs, and by preventing this has completely revolutionized surgical practice; nay, more, he has to a great extent revolutionized medicine, for the diseases of the internal organs, which were formerly entirely under the physician's care, are now becoming amenable to surgical treatment, and diseases of the stomach, intestine, liver, kidney, and lungs, and even of the brain and spinal cord, are now successfully treated by surgery when medicines are powerless to help. The most remarkable of all the recent triumphs of surgical operations upon the brain in which Mr. Horsley has gained such well deserved fame, would have been impossible without Ferrier's localization of cortical centres, and would have been equally impossible but for Lister's antiseptic method.

Disinfection.—But it is not only in surgery that recognition of diseased germs as a source of danger to the organism has led to their destruction outside the body, and insured safety from their attack. This occurs in all infective diseases, and this term now includes many which were not formerly regarded as such, for neither consumption nor pneumonia was formerly regarded in this light; but just about twenty-five years ago tubercle was shown to be inoculable, and since then the discovery of the bacillus of tubercle by Koch, and of pneumonia by Friedlander, has caused us to class both these diseases as not only infective, but as caused by definite organisms.

Prevention of Epidemic Diseases.—So long as people were ignorant of the causes of epidemic diseases, they were utterly unable to combat them, and they either in fury slew defenceless people for poisoning the wells, as in the Middle Ages, or appointed days of fasting and prayer, as in our own times. But once an epidemic is known to depend upon the presence of a certain organism, precautions can be taken for destroying the organism outside the body by means of disinfectants, or for lessening the susceptibility of the organism to its ravages inside the body by inoculation, or combating its effects by means of antipyretics. A knowledge of the life-history of microbes has enabled us to ascertain the power of different substances, either to destroy them completely or to arrest or retard their germination and growth, and in this way to prevent the occurrence of the diseases which these microbes might otherwise produce. . . .

Antivivisection.—Every now and again a loud outcry is raised against this method, partly from ignorance and partly from prejudice. Many—probably most—of the opponents of experiments on animals are good, honest, kind-hearted people, who mean well, but either forget that man has rights against animals as well as animals against man, or are misled by the false statements of the other class. These are persons who, blinded by prejudice, regard human life and human suffering as of small importance compared with those of animals, who deny that a man is better than many sparrows, and who, to the question that was put of old, "How much, then, is a man better than a sheep?" would return the reply, "He is no better at all." Such people bring unfounded charges of cruelty against those who are striving, to the best of their ability, to lessen the pains of disease both in man and also in animals, for they, like us, are liable to disease, and, like us, they suffer from it. I may perhaps be allowed to quote two sentences from a paper which I wrote twenty-four years ago, and therefore a considerable time before any antivivisection agitation had arisen, for they expressed then, and they express now, the objects of experimental pharmacology:—"Few things are more distressing to a physician than to stand beside a suffering patient who is anxiously looking to him for that relief from pain which he feels himself utterly unable to afford. His sympathy for the sufferer, and the regret he feels for the impotence of his art, engrave the picture indelibly on his mind, and serve as a constant and urgent stimulus in his search after the causes of the pain, and the means by which it may be alleviated" (*Lancet*, July 27, 1867).

Gains by Experiment on Animals.—It is said that our mouths are full of promises, but our hands are empty of results. The answer to this is, that anyone who doubts the utility of experimentation upon animals should compare the *Pharmacopœia* of 1867 with our present one. To it we owe, in great measure, our power to lower temperature, for to it is due not only the introduction of new antipyretics, such as salicylate of soda, antipyrin, antifebrin, and phenacetin, but the extension of the use of quinine from a particular kind of fever—malaria—to other febrile conditions. To it also we owe our greatly increased power to lessen pain by the substances just mentioned, which have not only an antipyretic but an analgesic action, and give relief in the torturing pains of neuralgia and locomotor ataxy when even morphine fails to ease, unless pushed to complete narcosis. The sleeplessness, too, which is such a frightful complication in some fevers, can now be combated by other remedies than opium and antimony; and we have the bromides, chloral, sulphonal, paraldehyde, urethane, chloralamide, and others, which, either by themselves or added to opium, enable us to quiet the brain instead of exciting it to further action, as opium alone so frequently does. Our whole ideas regarding cardiac tonics also have undergone a complete revolution within the last quarter of a century, for I was told, when a student, that digitalis was a cardiac sedative, and was apt to depress the heart, whereas now we know that it and its congeners—strophanthus and erythrophlœum and spartein—increase the heart's strength, raise the vascular tension, and are useful not only in sustaining the circulation, but in aiding elimination. This view of the action of cardiac tonics, which has revolutionized the treatment of heart disease, we owe chiefly to the experiments of Traube, although my own experiments, made in the laboratory of Sir Douglas Maclagan under the direction and by the help of my teacher and friend, Dr. Arthur Gamgee, may have helped towards its general acceptance in this country.

Future of Pharmacology.—But perhaps the most promising thing about pharmacology is that we are now just beginning to gain such a knowledge of the relationship between chemical structure and physiological action that we can, to a certain extent, predict the action of a drug from its chemical structure, and are able to produce new chemical compounds having a general action such as we desire; for example, anæsthetics, soporifics, antipyretics, analgesics, although we have not yet arrived at the point of giving to each one the precise action which would make it most suitable in any particular case. Even when we do not know the chemical structure of a drug, we may be able, from noticing one of its actions, to infer that it possesses others. We are, indeed, getting a knowledge of the action of drugs both of known and unknown chemical structure, and a power of making new remedies which will, I believe, enable us within the next five-and-twenty years to cure our patients in a way that at present we hardly think. . . .

THE INSTITUTION OF MECHANICAL ENGINEERS.

THE summer meeting of the Institution of Mechanical Engineers was held at Liverpool last week, commencing on Tuesday, the 28th ult., and concluding on Friday, the 31st ult. The President of the Institution, Mr. Joseph Tomlinson, presided throughout, and the meeting was highly successful, the long and varied programme being carried out with regularity and precision. The sittings for reading papers were held on the mornings of Tuesday and Wednesday; the afternoons of those days and also the Thursday and Friday being devoted to excursions. We will first deal with the papers and discussions.

The sittings were held in the concert-room of St. George's Hall, and the following list of papers was on the agenda:—A review of marine engineering during the past decade, by Alfred Blechynden, of Barrow-in-Furness; description of the warehouse and machinery for the storage and transit of grain at the Alexandra Dock, Liverpool, by William Shapton, of London; on the experimental engine and the alternative testing machine in the Walker Engineering Laboratories of University College, Liverpool, by Prof. H. S. Hele Shaw, of Liverpool; on the mechanical appliances employed in the construction of the Manchester Ship Canal, by E. Leader Williams, Engineer-in-Chief to the Canal Company. There was also a paper on the Liverpool water-works, but this was adjourned to the next meeting.

The Institution having been welcomed to Liverpool by the Mayor, Mr. J. B. Morgan, and the formal business having been transacted, Mr. Blechynden's paper was read. Mr. Blechynden has taken up the work commenced by Sir Frederick Bramwell at the Liverpool meeting of 1872, when the latter presented an historical paper giving a review of marine engineering up to that time. In 1881, the Institution met at Newcastle, when Mr. F. C. Marshall, a well-known Tyneside engineer, read a paper which consisted of a retrospect of the nine years since Sir Frederick Bramwell's paper had been read. We now have Mr. Blechynden carrying on the work. These periodical reviews are instructive. They cause the engineer to take stock of progress made, and enable him to see the lines upon which improvement may be expected to travel in the immediate future. Mr. Blechynden has been fortunate in the period which has fallen to his lot to review, for during the ten years past the triple compound engine has been developed. When Mr. Marshall read his paper, the ordinary compound engine with two cylinders was all but universal for steamships. Boiler pressures averaged 77·45 pounds per square inch, the average piston speed was 467 feet per minute, and the heating surface per indicated horse-power was 3·99 square feet. The consumption of coal per indicated horse-power was 1·828 pounds per hour. As a contrast to this, Mr. Blechynden tells us that at the present time the three-stage expansion engine has become the rule, and the boiler pressure has been increased to 160 pounds, and even as high as 200 pounds per square inch. Four-stage expansion engines of various forms have also been adopted. Forced draught has come to the front—largely, it would seem for the purpose of being abused—the piston speed has risen to 529 feet per minute, the heating surface per indicated horse-power is 3·274 square feet, and the coal consumption per indicated horse-power per hour is 1·522 pounds. By these figures it will be seen that during the last ten years the working pressure has about doubled, and that fuel economy has been improved by about 20 per cent. We may say that we do not always place full reliance in the details given with regard to fuel economy in connection with mercantile marine engines. We think that the power is apt to be taken on the best performance of the engines, so that they are credited with a duty they cannot maintain continuously throughout a voyage. Probably, however, the figures given by the author are accurate for comparative purposes, and they are not, as are some results claimed by marine engineers, altogether too good to be true. We would here draw attention to the author's expressions "three-stage" and "four-stage" compound engines. Engineers have been in the habit of referring to these types as triple expansion and quadruple expansion engines. This nomenclature is inaccurate and misleading for an ordinary two-cylinder compound, and even the simple non-compound engine expands the steam more than three or four times. Some engineers, recognizing this, have used the terms "triple compound" or "quadruple compound," but Mr. Blechynden's expression has the merit of greater accuracy and simplicity. We hope that engineers, who are apt to be somewhat loose in the naming of objects, will adopt Mr. Blechynden's terms. Added to the paper are tables giving details of construction and performance of representative steamers of the present day. A long discussion followed the reading of this paper. It turned chiefly upon the question of forced draught, corrugated flues, and the rules with regard to boiler testing which Mr. Sennett introduced when he was at the Admiralty. With regard to the forced draught question, the very sensible opinion seemed to have been arrived at that forced draught, though a good thing in itself, may prove a great ill if overdone. It is in the Navy chiefly that forced draught has gained an evil reputation, and naval officers are largely to blame for this, although the engineers must take their share of the responsibility. When it was found how great an accession of power could be obtained by forcing combustion with a fan, naval officers thought they had a royal road to speed. Boilers which had been designed on principles that had grown up under a simple chimney draught *régime*, were urged by fan-blast to duties beyond their powers of endurance; and then, when tube plates buckled and tubes leaked, forced draught was said by gallant admirals to be "the invention of the Evil One." The engineers, as we have said, were also to blame. The boiler has always been the Ishmael of the machinery-designer, nearly all the attention having been lavished on the engine. As a consequence boiler construction has been a matter of rule of thumb, and, when the empirical rules upon which it was based have no longer applied, the engineer has been nonplussed through want of a basis of scientific knowledge upon which to build anew. The torpedo-boat builders have no trouble with forced draught, though they blow far harder than in any other vessels; but then the torpedo-boat builders are good engineers—not mere blind followers of "practice"—as was proved by the paper read last spring on this subject by Mr. Yarrow before the Institution of Naval Architects. In speaking upon corrugated flues Mr. Macfarlane Gray made a remark on the subject which might have received more attention. It has long been claimed by the makers of this type of furnace that additional heating surface, and that of a most valuable kind, was obtained by the corrugations. This Mr. Gray said was a fallacy, for the heat from the furnace proceeded only in radial lines, and therefore no greater effective area of heating surface could be obtained than that due to a plain cylinder.

Mr. Shapton's paper was an interesting description of the building and machinery referred to in the title, by which grain is transported and stored. The warehouse in question consists chiefly of a vast cellular structure which might be described as a brick and mortar honeycomb, filled with grain in place of honey. There are 250 hexagonal bins or silos, each measuring 12 feet across the angles and 80 feet deep. The storage capacity is 2,240,000 bushels. The grain is lifted from vessels by elevators, and carried to the top of the building, from whence vertical movement is supplied by gravity. Horizontal travel is carried on by continuous moving belts or bands which run over wheel pulleys. The way in which streams of grain can be diverted into any required direction is very curious to watch. A good part of the discussion on the paper turned on the best form of bin or silo. At first one would think that the bin designer could not do better than follow the bee, but it was shown that cylindrical chambers made of sheet iron would give a large saving of space over the hexagonal brick bins. The advantage is due of course to the thinner walls of sheet iron, the cylinder being a form by which advantage can best be taken of the high tensile strength of iron. In America, where the silo system was in common use long before it made its appearance in this country, the bins are made wholly of wood, but this is subject to rot, and harbours weevils. Sheet-iron rusts and brick retains moisture, so that with brick the grain heats unless well looked after and ventilated. On the whole, however, brick has the preference in this country. Sir James Douglass made a suggestion which will, we should think, receive attention at the hands of future silo designers. The representation of the Eddystone Lighthouse at the Royal Naval Exhibition is a building not altogether dissimilar from a silo. It has very thin walls, which are constructed of expanded sheet steel, or sheared lattice work, which forms the bond for a crust of Portland cement. The result is a wall of great tenacity and rigidity, and one which would not have the same defect as brickwork with regard to harbouring damp. The problem of ventilating grain is

Digitized by Google

one of difficulty; and it may be said that it has not yet been solved. The most serious effort yet made was the building of a granary on the banks of the Thames, known, we believe, as the Patent Ventilating Granary. This granary was referred to during the discussion by Mr. Percy Westmacott, so long the chief of the hydraulic department at Armstrong's. The patent ventilating arrangement consisted of a perforated tube running down the centre of each bin. This was provided with a movable stop or plug, and, by adjusting the height of the stop, a blast of air could be directed through the perforations of the tube into any part of the grain. The idea was of French origin, and, Mr. Westmacott said, more ingenious than practical, so that the granary was pulled down after a time. It is easy to understand that those parts of the grain which required most ventilation would form into hard lumps, into which the air would not penetrate. As a matter of fact it is found more advantageous to air the grain by giving it a constitutional over the carrying bands.

Prof. Hele Shaw's paper on his experimental engine and alternative centre-testing machine was one of great interest. The engine in question, which is described as a marine engine, though it has a large fly-wheel, is, we believe, the most elaborate from an experimental point of view, yet made. The question has been raised whether it is not too elaborate, so that satisfactory results will not be reached on any one point. That is a problem which remains to be proved by facts; for the engine has only just been erected. It is 150 horse-power, and is of the ordinary vertical three-cylinder three-stage compound type. The high-pressure and intermediate cylinders have cylindrical valves, and the low pressure has a flat valve. Each valve is worked by a different type of motion—namely, ordinary Stephenson link motion, Joy gear, and Hackworth gear. The cylinders are jacketed at sides and ends, and there are provisions in the way of connections for working in every possible manner, *i.e.* cylinders all jacketed, not jacketed at all, or any one or two jacketed. Any combination of cylinders can be worked, or any one cylinder alone. In addition to this the cranks are adjustable on their shaft, so that any combination can be got in this way; in short, the number of different combinations that are at command would require years to work through. There are the usual measuring tanks and other apparatus for quantitative tests. An excellent suggestion was made by Prof. Goodman during the discussion. He proposed that arrangements should be made for testing the students' knowledge by putting the engine into conditions not in accordance with proper design. For instance, he would have valve-rods or excentric rods of improper length, valves ill-set with improper lap or lead, leaky valves and pistons, and various other ills, to which engines are subject, purposely introduced. He would also provide a means of passing water into the cylinders. He would then have the student take diagrams from the engine, and leave him to determine the cause of the defect by the appearance of the cards. We hope Prof. Goodman will be able to follow up this useful suggestion in his own laboratory at Leeds. The alternative testing machine is a 100-ton single-lever machine of the Wicksteed type. The alteration in power is got by substituting one fulcrum for another a few inches distant. The mechanism by which this is done is ingenious, but the details would be difficult to explain without the aid of diagrams.

The last paper read at the meeting was that of Mr. Leader Williams. The author commenced by saying that 46½ million cubic yards had to be excavated in making the Manchester Ship Canal, and as only 17,000 men and 200 horses have been used there was evidently required a large power in the shape of mechanical appliances in order to get the work done in anything like reasonable time. Ninety-seven steam excavators and eight steam dredgers of large power have been employed; and the spoil has in most cases been taken a distance of several miles. For this work, and for the general purposes of construction, 173 locomotives and 6300 trucks and waggons have been used. The railways laid for the purpose amount to 228 miles of single line. The rate of excavation has varied from three-quarters of a million to 1¼ million cubic yards per month. There are also employed on the works 124 steam-cranes, 192 portable and other steam-engines, and 212 steam-pumps. The coal consumed by the engines is about 10,000 tons a month. These figures will give some idea of the heroic proportions upon which large constructive works are carried out, and the capital required to start them. The whole plant of the Manchester Ship Canal has cost, we believe, close on a million sterling. The machines described in the paper which were of greatest interest were the excavators. The chief of these is the now well-known "steam navvy," made by Ruston and Proctor, of Lincoln. It first came prominently into notice during the construction of the Albert Docks, and is looked on as a standard tool wherever large excavating work is undertaken. It has the immense advantage of being able to work in any kind of soil, even including sandstone rock, if not very hard. It is only in hard rock that blasting has to be done as an auxiliary. The most interesting, or, perhaps, we should say the most novel machines are the French and German excavators, or land dredgers, which have been introduced into this country for the first time in connection with this work. These are on the same general principle as a floating ladder and bucket dredger of the common type. In place of the ladder and motive machinery being held by a floating hull, there is a small house mounted on wheels, and this runs on a line of rails on the summit of a bank. The ladder slopes outward from the side, reclining on the bank, which the buckets scrape away as they traverse, and deposit the spoil in waggons on the bank above. There are differences in detail between the French and German types, but in general principle they are alike. The German machine appears to us the better designed, but Mr. Leader Williams says the French excavator is of more substantial construction. The weight of these machines is from 70 to 80 tons, and under favourable conditions they have been known to excavate the enormous bulk of 2400 cubic yards in one working day. Mr. Williams's paper was not discussed, which is a fact to be regretted by engineers, as the subject is one which requires ventilation; but time was running short. After the usual votes of thanks, the sittings of the meeting were brought to a close.

We can only add a few words about the excursions. On the Tuesday there was a lunch on board the big White Star liner the *Majestic*, for one section of the members; whilst others visited the grain warehouse, described by Mr. Shapton in his paper, and the new overhead railway, which has been designed by Mr. Greathead, the Engineer of the City and South London Railway, and which runs along the line of docks. This railway is of steel and iron throughout, and possesses the novel advantage of forming a water-tight roof, under which the people of Liverpool will be able to walk on rainy days without getting wet. In the evening there was a *conversazione*, which, of course, was the social feature of the meeting. On Wednesday afternoon the members visited the new engineering laboratories which have been added to University College, Liverpool, where the engine and testing machine described in Prof. Hele-Shaw's paper were examined. On Thursday one party visited the Mersey Docks, the Mersey Tunnel, and Laird Bros.' ship-yard and engine works. At the latter there are several interesting vessels in progress, including the big battle ship *Royal Oak*, of 14,000 tons. Another party went to Horwich, and saw the fine locomotive works which have just been completed there by the Lancashire and Yorkshire Railway. These works have been beautifully planned and laid out under the superintendence of Mr. Aspinall. Although not so large as some other establishments of a similar kind, they may be taken as a model of design. Mr. Aspinall naturally had a unique opportunity with a clear field to work upon, and an accumulated experience at his command. Friday, the last day, was devoted wholly to the Manchester Ship Canal, the members being carried down the line of works in a special train, under the guidance of Mr. Leader Williams.

THE NEW GAS, CHLOROFLUORIDE OF PHOSPHORUS.

AS briefly announced in the report of the proceedings of the French Academy of Sciences, a note upon a new gaseous compound, containing phosphorus, fluorine, and chlorine, has just been presented by M. Moissan, on behalf of M. Poulenc. During the course of his work upon the fluorides of phosphorus, M. Moissan observed that, when phosphorus trifluoride was brought in contact with chlorine, the green colour of the latter at once disappeared, and there appeared to be formed a new and colourless gas. The gas thus formed has been prepared in considerable quantity by M. Poulenc, and its properties investigated. It appears to be directly formed by addition, according to the simple equation—

$$PF_3 + Cl_2 = PF_3Cl_2;$$

Digitized by Google

for the trifluoride of phosphorus and chlorine are found to react in equal volumes, and the combination is attended by a contraction of one-half. The new gas may therefore be considered as phosphorus chlorofluoride, PCl_2F_3, the chlorine derivative of phosphoryl and thiophosphoryl fluoride, POF_3 and PSF_3.

The most convenient mode of preparation is described as follows. Two flasks of equal capacity (about 500 c.c.) are taken, and filled respectively with phosphorus trifluoride and chlorine. They are connected together by a bent tube passing through the stoppers, and the flask containing the phosphorus trifluoride is further connected with a reservoir of mercury in such a manner that a gentle pressure may be placed upon the trifluoride, so as to gradually displace it over into the chlorine. The two flasks being of equal capacity, it is evident that, when the whole of the trifluoride has thus been transferred, the reaction is completed, the green colour of the contents of the other flask disappears, and the remaining gas is almost pure chlorofluoride. After allowing to stand a few days in contact with the mercury, in order to remove the last traces of chlorine, the gas is ready for examination.

Phosphorus chlorofluoride is a colourless incombustible gas, possessing a powerfully irritating odour. It is instantly absorbed and decomposed by water and by solutions of alkaline or alkaline earthy hydrates. A determination of its vapour-density gave the number 5·40, sufficiently near the theoretical density of a substance PCl_2F_3 (5·46). It is comparatively easily liquefied, a temperature of $-8°$ C. being sufficient at ordinary pressures. It is dissociated at a temperature of 250° C. into gaseous pentafluoride and solid pentachloride of phosphorus. The induction spark effects the same decomposition.

Sulphur reacts with phosphorus chlorofluoride in a most interesting manner. The reaction commences about the melting-point of sulphur, 115° C., and the products are chloride of sulphur and gaseous thiophosphoryl fluoride, PSF_3. And here a most emphatic protest must be made against the manner in which many French chemists persistently ignore the work of the chemists of other countries. Thiophosphoryl fluoride, PSF_3, was discovered and prepared three years ago in the Research Laboratory of the Royal College of Science, South Kensington, by Prof. Thorpe and Mr. J. W. Rodger; and a detailed account, illustrated by experiments, of the mode of preparation and properties of this remarkable gas, was laid before the Chemical Society and published in their Journal.[1] And yet, in the memoir just presented by M. Moissan, we find this compound, a description of which long ago found its way into the abstracts or referate of most foreign journals, described as "un nouveau composé gaseux." Indeed, a considerable amount of unnecessary trouble appears to have been taken in order to ascertain the composition of this "new gas"—trouble which, as the compound is so readily recognizable by its extraordinary properties, might have been saved, if the author had taken the pains to look up the literature of the subject. It is high time that French chemists should look to their "prestige" in this respect, for, unfortunately, the present is by no means the only case which has within the last few months come before the notice of the writer of this note, in which compounds fully described and worked out by English chemists have been rediscovered and described as new by French authors.

When phosphorus chlorofluoride is passed over free phosphorus heated to 120°, it is decomposed with formation of phosphorus trifluoride, which passes away as gas, and phosphorus trichloride, which condenses in liquid drops. Metallic sodium, when slightly heated, appears to absorb the chlorofluoride entirely, while magnesium, aluminium, iron, nickel, lead, and tin, when heated to about 180°, attack the gas with formation of anhydrous chlorides and liberation of phosphorus trifluoride. Mercury attacks it very slowly at the ordinary temperature, but very rapidly at 180°, with formation likewise of a chloride of the metal and gaseous trifluoride of phosphorus. Hence, when purifying the gas from the last traces of chlorine, the mercury should not be agitated, but allowed to remain at rest, as agitation brings about a perceptible amount of decomposition.

Water reacts in two stages with phosphorus chlorofluoride. When a little aqueous vapour is admitted into the vessel inclosing the gas, phosphoryl fluoride and hydrochloric acid are formed in accordance with the equation—

$$PCl_2F_3 + H_2O = POF_3 + 2HCl.$$

When passed into water, however, the gas is completely decomposed into phosphoric, hydrochloric, and hydrofluoric acids—

$$PCl_2F_3 + 4H_2O = H_3PO_4 + 2HCl + 3HF.$$

Ammonia gas reacts at the ordinary temperature with production of a white solid compound, readily soluble in water, which appears to be fluophosphamide, $PF_3(NH_2)_2$.

$$PCl_2F_3 + 4NH_3 = PF_3(NH_2)_2 + 2NH_4Cl.$$

Phosphorus chlorofluoride is absorbed by absolute alcohol with production of a compound possessing a penetrating odour, and which burns with a bright flame bordered with green, and leaves a white residue of phosphoric acid. The nature of this compound has not yet been fully ascertained.

These properties of phosphorus chlorofluoride indicate that the gas is much less stable than the pentafluoride, and that the two atoms of chlorine possess a mobility which renders their removal a matter of considerable ease. A. E. TUTTON.

[1] Journ. Chem. Soc. Trans, 1889, vol. lv. p. 305.

PROF. MENDELEEFF ON THE VARIATION OF THE DENSITY OF WATER AT DIFFERENT TEMPERATURES.

THE last number of the Journal of the Russian Physical and Chemical Society (1891, No. 5) contains an important paper, by Prof. Mendeleeff, upon the variation of the density of water at different temperatures. In a work, published in 1884 and translated into English in the Journal of the Chemical Society, the Russian Professor proposed the formula $S_t = S_0(1 - kt)$ as a first approximation to a mode of expressing the expansion of liquids at a certain distance from the temperatures at which they change their state, and within the limits of accuracy attained in the present determinations. But he remarked that the expansion of water would require a separate formula, and he now proposes the formula

$$S_t = 1 - \frac{(t-4)^2}{(A+t)(B-t)C},$$

which embodies, with sufficient accuracy, all that is yet known about changes in the density of water (S_t) within the limits of from $-10°$ to $+200°$. For all liquids save water, the increase of density with the increase of temperature, that is, the derived $\frac{ds}{dt}$, varies but little; it but slightly increases or slightly decreases with considerable changes of temperature; while for water, $\frac{ds}{dt}$ not only changes its sign at $+4°$, but very rapidly varies even at temperatures remote from zero, and even superior to 100°. After confirming the above by a few examples, Prof. Mendeleeff indicates the faint relations between his new formula for water and the general law of the expansion of liquids, by explaining the way in which he arrived at his new formula. He points out, moreover, that under the present state of the determinations of the density of water at various temperatures, it would be impossible to find exact figures for the constants A, B, and C, in the above formula, and that provisionally, and especially for temperatures between 0° and 40°, they may be taken as follows:—A = 94·10, B = 703·51, and C = 1·90.

Prof. Mendeleeff then goes on briefly to analyze the various corrections which ought to be taken into account in the determinations of the density of water; namely, the influence of pressure, the expansion of solids, and the measurements of temperature. All these being taken into account, it appears that the errors of the best determinations of densities attain several units in the fifth decimals, even at common temperatures. After many unsuccessful attempts at improving the current figures of densities by introducing into them several corrections, Prof. Mendeleeff abandoned the idea, and he now gives the authentic figures, as they were published by the investigators themselves, simply expressing all determinations in volumes for the sake of facilitating comparison. The figures published by Hallstrom (1823), Muncke (1828), Stampfer (1831), Despretz (1837), Pierre (1847), Kopp (1847), Plücker and Geissler (1852), Hagen (1855), Henrici (1864), Jolly (1864), Matthissen (1865), Weidner (1866), and Rosetti (1869), are thus given in a first table. The figures, as they were corrected by Biot in 1811, Hallström in 1835, Miller in 1856, Rosetti in 1871, Volkmann in 1881, Mendeleeff in 1884, and Makaroff in 1891, are given in a second table.

The averages of the volumes of water derived from the original

Digitized by Google

figures (Table I.), at temperatures from − 5° to + 100°, taking the volume at 4° equal to 1,000,000, and the pressure being equal to one atmosphere, appear as follows in the second column (V_t) of the subjoined table. They are followed, in the third column, by the volumes as calculated from Prof. Mendeleeff's new formula :—

t.	V_t	$V_t = \frac{1}{S_t}$ calculated from the formula.	$\frac{dV}{dt}$ for 1°.	$\frac{dV}{dp}$ for 1 atmosphere.	Possible errors of the present determinations.
− 5	1 000 662	1 000 676	− 157	− 52	∓ 29
0	1 000 122	1 000 127	− 65	− 50	∓ 12
+ 5	1 000 008	1 000 008	+ 15	− 48	± 3
10	1 000 263	1 000 262	+ 85	− 47	± 15
15	1 000 847	1 000 849	+ 148	− 46	± 26
20	1 001 733	1 001 731	+ 204	− 45	± 35
25	1 002 871	1 002 880	+ 254	− 44	± 43
30	1 004 248	1 004 276	+ 302	− 43	± 49
40	1 007 700	1 007 725	+ 356	− 41	± 59
50	1 011 933	1 011 967	+ 461	− 40	± 67
60	1 016 915	1 016 926	+ 530	− 39	± 75
70	1 022 513	1 022 549	+ 595	− 40	± 85
80	1 028 849	1 028 811	+ 656	− 41	± 98
90	1 035 719	1 035 692	+ 719	− 42	± 118
100	1 043 180	1 043 194	+ 781	− 44	± 145

Finally, a third table is given, being the result of the calculation made by taking

$$S = 1 - \frac{(t-4)^2}{1000\phi(t)},$$

$$\phi(t) = 128{\cdot}78 + 1{\cdot}158t - 0{\cdot}0019t^2,$$

and

$$1000\phi(t) = 1{\cdot}90\,(94{\cdot}10 + t)\,(703{\cdot}51 - t),$$

and extending the calculation to + 200° and − 10°. The most important values of $\frac{ds}{dt}$ are given in the fourth column of the subjoined table ; so, also, the approximate values of $\frac{ds}{dp}$, which are "but a first rough approximation," to show the importance of pressure in the determinations of volumes of water :—

° C.	Calculated densities, S_t.	Possible error of present measurements (in 1,000,000th parts).	Derived ds/dt for 1° C. (in 1,000,000th parts).	Derived ds/dp for 1 atmosphere (in 1,000,000th parts).	Numerical values of $\phi(t)$.	Calculated V_t.
− 10	0·998 281	∓ 49	+ 264	+ 54	114·01	1·001 722

90	965 537	109	− 670	41	214·61	035 692
100	958 595	133	− 718	42	222·58	043 194
120	943 314	±600	− 810	+ 43	237·38	1·060 093
140	926 211	650	− 901	48	250·66	079 667
160	907 263	700	− 995	55	262·42	102 216
180	886 393	750	− 1093	64	272·66	128 167
200	863 473	800	− 1200	73	281·38	158 114

In conclusion, Prof. Mendeleeff repeats that he proposes as soon as possible to make anew the determinations of the densities of water, because the former determinations were made on assumptions (permanency of the coefficient of the expansion of glass and mercury, and no notice being taken of pressure) which can no longer be maintained. If new measurements confirm the formula, or lead to a more correct one, we shall be better able to understand the laws of the expansion of all liquids, and therefore of gases as well. "In the case of water," he says, "we have begun to understand more clearly the influence of heat upon densities and volumes, and I believe that with the help of water we may expect some further progress in the study of the influence of heating upon matter."

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The examiners in the Final Classical Schools issued the Class List on Wednesday week, completing the results of the examinations held in Trinity Term.

The summer meeting of Extension students commenced on Friday last, when Mr. Frederic Harrison, M.A. Wadham College, delivered the inaugural lecture. The popularity of the movement is proved not only by the continual increase in the number of students who avail themselves of the advantages offered by this system of education, but by the interest which foreign Governments are taking in the development of the plan. The French Government have sent two special commissioners to report on the prospects and condition of the University Extension movement, and a large number of the representatives of the American University Extensionists are now in Oxford.

The number of students attending the various lectures is greater than on any previous occasion, more than 1100 having subscribed, while last year the number did not greatly exceed 900. A more rapid growth and a still greater measure of success attending the work may be anticipated from the fact that various County Councils, finding themselves in possession of funds arising from the operation of the Local Taxation Act, and which they propose to devote to the purposes of technical instruction, are availing themselves of the machinery of the University Extension system to accomplish this desirable end.

SCIENTIFIC SERIALS.

IN the *Botanical Gazette* for June, Mr. T. Holm contributes a study of some anatomical characters of North American grasses. In a paper entitled "On the Relation between Insects and the Forms and Characters of Flowers," Mr. T. Meehan epitomizes his views on fertilization opposed to the current theory, viz. that the part played by insects in the fertilization of flowers has been greatly exaggerated ; that flowers do not abhor cross-pollen ; and that all annuals can self-fertilize when cross-fertilization fails, annuals in almost all cases having every flower fertile.

THE most important paper in the *Journal of Botany* for July is the commencement of a detailed account of the Algæ of the Clyde sea-area, by Mr. George Murray, Secretary to the Committee for the Exploration of the Marine Flora of the West of Scotland. This is prefaced by an account of the physical features of the Clyde sea-area, by Dr. John Murray. Following this is the commencement of a hand-list of the Algæ, by Mr. E. A. L. Batters. The Rev. H. G. Jameson concludes his key to the genera and species of British mosses, which it is hoped may be published in a separate form ; and Mr. George Murray sinks Hooker's genus of sea-weeds *Cladothele* in *Stictyosiphon*.

SOCIETIES AND ACADEMIES.

PARIS.

Academy of Sciences, July 27.—M. Duchartre in the chair. —Proofs that Asia and America have been connected in recent times, by M. Emile Blanchard. In this paper the author points out certain species of Asiatic fauna and flora which are found in North America, as, in the preceding one, he indicated the representatives of European fauna and flora which occur in the same continent. Without making an extensive enumeration of the

Digitized by Google

different species, the facts brought forward give considerable support to the idea that Europe, Asia, and America have been connected by land in comparatively recent times.—The Ichthyosaurus from St. Columbe, by M. Albert Gaudry. This is a description of an Ichthyosaurus exhibited at the Paris Exhibition of 1889. It is proposed to name the fossil *Ichthyosaurus burgundiæ*.—Examination of samples of native iron of terrestrial origin discovered in gold washings from the environs of Berezowsk, by MM. Daubrée and Stanislas Meunier. The specimens examined weighed respectively 11·5 grams and 72 grams, and were discovered near the Berezowsk gold mines, Persia. The metal is very magnetic, but manifests no polarity. Its density is 7·59. When treated with an acid it is sensibly attacked, but does not show the Widmanstätten figures as is the case when acid is applied to a clean face of meteoritic iron. This fact and the absence of nickel leads the authors to conclude that the iron is truly native. About one per cent. of platinum is present.—On the volatility of nickel under the influence of hydrochloric acid, by M. P. Schützenberger. When dry hydrogen is passed over pure anhydrous nickel chloride at a red heat, it may be shown that the hydrochloric acid gas which comes off from the tube in which the reduction occurs contains a sensible amount of metal in the form of a volatile product. The same result is obtained if, instead of reducing nickel chloride by hydrogen, finely divided nickel is acted on by dry hydrochloric acid gas. M. Schützenberger has not yet been able to isolate this body for the purpose of determining its constitution.—Note on a proposed Observatory on Mont Blanc, by M. J. Janssen.—On the retardation of luminous impressions, by M. Mascart.—Works of applied zoology effected at the Endoume maritime station during 1890, by M. A. F. Marion.—On a geometrical representation and formula expressing the law of the passage of perfect gases through orifices, by M. Henri Parenty.—On the densities of oxygen, hydrogen, and nitrogen, by M. A. Leduc. The values obtained are: hydrogen 0·0695, oxygen 0·1050, nitrogen 4·9720. From the densities of oxygen and nitrogen the percentage proportion of the former element in air is found to be 23·235 by weight and 21·026 by volume. The atomic weight of nitrogen deduced from these results is 13·99, and that of oxygen 15·905.—Remarks on the transport of metallic iron and nickel by carbon monoxide, by M. Jules Garnier. Some observations of the character of the flames issuing from furnaces in which these metals are being reduced are shown to be easily explained in the light of recent work on iron and nickel carbonyls.—Action of water on the basic salts of copper, by MM. G. Rousseau and G. Tite. Certain borates and oxychloride of antimony are transformed to oxides by the prolonged action of water at a sufficiently high temperature. Similarly, by heating copper nitrate, brochantite, and atacamite with water in sealed tubes they have been reduced to oxides. Libethenite has been experimented upon, but has resisted the transformation even when kept in the presence of water for three days at a temperature of 273° C.—On an actual mode of formation of mineral sulphides, by M. E. Chuard.—Researches on thallium, by MM. C. Lepierre and M. Lachaud. Thallium chromate has been prepared by acting on thallium sulphate with potassium chromate. Reactions with various bodies are described.—On parabanic and oxaluric acids, by M. W. C. Matignon. The heat of combustion of parabanic acid is found to be 212·7 cal., of oxaluric acid 211 cal. Hence the heats of formation have been calculated, 139·2 cal. and 209·9 cal. The heat of solution of parabanic acid at 20° and with a concentration of $\frac{1}{20}$ mol. per litre is − 5·1 cal. The formation from oxalic acid of its ureide, parabanic acid, gives + 2·2 cal. and of its uramic acid, oxaluric acid, + 2·5 cal. The formation of the ureides thus gives only a feeble heat-liberation. Each of these acids dissolved in a large excess of potash yields the neutral potassium oxalate. Potassium oxalurate has been prepared by dissolving the acid in its equivalent of potash and evaporating. Fine prismatic needles are obtained, differing from the salts of Menschutkin and Strecker. The heat of neutralization of oxaluric acid is 30·2 cal., as against 34·2 cal. for oxalic acid.—The transformation of gallic acid and tannin into benzoic acid, by M. Ch.-Er. Guignet.—On the polymeric acids of ricinoleic acid, by M. Scheurer-Kestner.—On the fermentation of bread, by M. Léon Boutroux. During an examination of the conditions essential for the fermentation of bread, the author has isolated five species of yeast and three species of bacteria. The parts played by each of these organisms are described, and the conclusion is finally drawn that the fermentation of bread consists essentially of a normal alcoholic fermentation of sugar pre-existing in the flour, and that only the yeasts producing alcoholic fermentations are necessary; the ordinarily co-existing alteration of gluten is a subsidiary and unessential action due to some of the bacteria present.—On a thermogenic substance in urine, by M. Paul Binet.—On the transformation of carboxy-hæmoglobin into methæmoglobin, and a new process of examination for carbon monoxide in the blood, by MM. H. Bertin-Sans and J. Moitessier.—On a new apparatus for measuring muscular power, by M. N. Gréhant.—Measure of the muscular power of animals under the action of certain poisons, by MM. Gréhant and C. Quinquaud.—On the concordance of Prof. S. P. Langley's experimental results on the resistance of the air (see NATURE of July 23, p. 277) with the values obtained by calculation, by M. Drzewiecki.—Analysis by means of chrono-photography of the movements of the lips during speech, by M. G. Demeny. Using M. Marey's method for photographing objects in rapid motion, the author has succeeded in portraying the movements of the lips during speech, and finds that it is possible to distinguish the letters of the alphabet when the photographic results are spun in a zootrope.—Relation between oscillations of the retina and certain entoptic phenomena, by M. A. Charpentier.—The nanny-goat is not refractory to tuberculosis, by M. G. Colin.—Researches on the pathogenic microbes in muds from the Dead Sea, by M. L. Lortet.—On the excretory apparatus of Caridiæ, and on the renal secretion of Crustaceæ, by M. P. Marchal.—On the nervous system of Monocotylidæ, by M. G. Saint-Remy.—Contribution to the natural history of a cochineal, *Rhizœcus falcifer*, Künck, discovered in the greenhouses of the Museum and living on the roots of the vine in Algeria, by MM. Kunckel d'Herculais and Frédéric Saliba.—On specific assimilation in Umbelliferæ, by M. Génean de Lamarlière.—Document relative to the trajectory of the Ensisheim meteorite of 1492, by Prof. H. A. Newton.—On the erosion and transport by torrential rivers having glacier affluents, by MM. L. Duparc and B. Baeff.

MACMILLAN & CO.'S PUBLICATIONS.

8vo, Cloth, 14*s.* net.

THE HISTORY OF HUMAN MARRIAGE.

By EDWARD WESTERMARCK, Ph.D.,

Lecturer on Sociology at the University of Helsingfors.

TIMES:—"Very learned and elaborate, scientifically conceived and scientifically executed. It should command the serious attention of all scientific students of sociology."

MANCHESTER GUARDIAN:—"In his introduction to this book Mr. Wallace, than whom there could scarcely be a better authority, says that he has seldom read 'a more thorough or a more philosophic discussion of some of the most difficult and at the same time interesting problems of anthropology.' And a perusal of the book will most assuredly convince the reader that the great naturalist's verdict is fully justified. Mr. Westermarck has established his position among the first of historical anthropologists, he has thrown light upon many of the unsolved mysteries in the history of the human race, and he has swept out of the way several theories which have hitherto blocked the path to a right solution of the main questions at issue. . . . Clearly and becomingly written, based upon a very wide and well-chosen course of reading and investigation, the book affords a model for future investigators in this field."

NATIONAL OBSERVER:—"He has conducted his inquiry concerning human marriage with spirit, industry, and intelligence. He has left few authorities unconsulted, and his facts are handled and arranged with infinite skill. Upon many points he differs from his predecessors; but the world has been so hasty in adopting McLennan's theory as a demonstrated truth that opposition is the healthiest progress. Mr. Westermarck's main contention is that marriage is an ancient and universal custom, and that promiscuity is not a necessary step in the development of mankind. . . . Though many will reserve their judgment, all will confess that Mr. Westermarck's treatise is an invaluable contribution to science. . . . We confidently recommend Mr. Westermarck's 'History of Marriage' not only to all anthropologists but to all them that love good reading."

ANTI-JACOBIN:—"There can be no doubt of the courage of a hitherto unknown student who comes from the comparatively obscure University of Finland to throw down the gauntlet before warriors of such prestige as Darwin, Spencer, Tylor, Lubbock, and McLennan; but intelligent students of Mr. Westermarck's volume will acquit him of temerity, and, indeed, it is more than possible that, as Mr. Alfred Wallace predicts in his introduction, 'the verdict of independent thinkers will be in favour of the newcomer.' . . . . A book which is far too rich in the detailed products of laborious research to be treated at once briefly and adequately. It is certainly the most valuable of recent contributions to the literature of a deeply-interesting theme; and not the least of its recommendations is that, while it necessarily deals with many delicate topics, the handling is absolutely reproachless on the score of taste."

LIVERPOOL DAILY POST:—"Since the appearance of Mr. McLennan's work on 'Primitive Marriage' there has been no study of the manners and habits of savage races that in point of originality can compete with Mr. Westermarck's 'History of Human Marriage.' . . . There is every reason to suppose that this deeply interesting book will find a host of readers even among those who are attracted by facts for their own sake rather than for the theories that may be drawn from them."

NEW VOLUME OF NATURE SERIES.

Just ready, 8vo, Cloth, 4*s.* 6*d.*

THE RIGHT HAND: LEFT HANDEDNESS. By Sir DANIEL WILSON, LL.D., F.R.S.E., President of the University of Toronto.

Just ready, 8vo, Cloth, 12*s.* net.

THE POSITIVE THEORY OF CAPITAL. By EUGEN V. BÖHM-BAWERK, Counsellor in the Austrian Ministry of Finance, and Honorary Professor of Political Economy in the University of Vienna. Translated, with a Preface and Analysis, by WILLIAM SMART, M.A., Lecturer on Political Economy in Queen Margaret College, Glasgow.

NEW EDITION, REVISED.

Crown 8vo, Cloth, 10*s.* 6*d.*

A COURSE OF PRACTICAL INSTRUCTION IN BOTANY. By F. O. BOWER, D.Sc., F.R.S., Regius Professor of Botany, Glasgow.

NATURE:—"Everyone perusing the volume must be impressed with the high standard of its educational value. Teacher and student in this country are alike to be congratulated upon its publication."

ACADEMY:—"The work is one which should be in the hands of every practical botanist."

SATURDAY REVIEW:—"The types are good, easily obtained, and thoroughly worked out. . . . There is no padding, the text is to the point, and it assumes the presence of the plant concerned and the instruments in hand. We regard the absence of illustrations and of descriptive padding as important preventives of cram, and it should be clearly borne in mind that laboratory teaching suffers especially by the opening up of royal roads."

BY SIR ARCHIBALD GEIKIE, LL.D., F.R.S.

New and Revised Edition. Globe 8vo, 3*s.* 6*d.*

OUTLINES OF FIELD GEOLOGY. By Sir ARCHIBALD GEIKIE, LL.D., F.R.S., Director-General of the Geological Survey of Great Britain and Ireland.

"*This volume has now been thoroughly revised and considerably enlarged. One of the chief changes will be found in the account of the schistose rocks, which has been re-written in the light of recent researches into these interesting but difficult parts of the geological record. A number of new illustrations have been added from my note-books.*"—From the Author's Preface.

MACMILLAN AND CO., LONDON.

NEW AND INTERESTING MICROSCOPIC OBJECTS.

Special Set of 36 Objects arranged for Students *v. p.* for the Diploma of Public Health, as mentioned in Dr. Allan's "Aids to Sanitary Science"—in box 50 0
Sections of Spine of Echinus (*Echinus esculentus*) 1 6
Harvest Bug (*Trombidium autumnale*) 1 6
Blight of Grape Vine (*Phylloxera vastatrix*, winged) 3 0
Complete Anatomy of Honey Bee—various parts dissected and laid out separately on one Slide ... 6 0
New Type Slide of Diatomaceæ—50 different Species, with List of Names 10 6
Diatomaceæ from St. Peter, Hungary—about 200 Specimens on one Slide 6 0
New and very pretty Slide of Sponge Spicules, containing about 100 Specimens from St. Peter, Hungary 2 6
New Slide of Sponge Spicules, containing about 100 Specimens (*Hyalonema mirabile*) 2 6
Bacillus tuberculosis in Sputum 3 0
Do. of Asiatic Cholera 5 0
Do. *anthracis* in Section of Liver 3 0
Very Perfect Section across entire foot of Fœtus, showing Ossifying Cartilage, &c. 3 6
Section of Chalcedony—very Fine, for Polariscope 1 6
Section of Leaf of Hemp, showing Bast Cells—double stained 1 6
Entire Drone Bee 2 0

London: WEST, NEWMAN, & CO., 54 Hatton Garden.

On the 1st of every Month.

JOURNAL OF BOTANY,

BRITISH AND FOREIGN.

Edited by JAMES BRITTEN, F.L.S., British Museum.

CONTENTS:—Original Articles by leading Botanists.—Extracts, and Notices of Books and Memoirs.—Articles in Journals.—Botanical News.—Proceedings of Societies.

Price 1s. 3d. Subscription for One Year, payable in advance, 12s.

London: WEST, NEWMAN, & CO., 54 Hatton Garden, E.C.

F. H. BUTLER, M.A. Oxon., Assoc.R.S.Mines,

NATURAL HISTORY AGENCY,

158 BROMPTON ROAD, LONDON,

Dealer in Rocks, Minerals, Fossils, and other Objects of Scientific Interest.

The Specimens recently added to Stock include examples of the rare Cæsium mineral Pollucite, from Maine, also of Beryllonite and Hiddenite, U.S.A.; fine sections of Siphonia in Flint; Fossils and Sedimentary and Igneous Rocks from the Llanlovery, Caradoc, Llandeilo, Wenlock, and Upper Lingula Beds near Builth, Church Stretton, and Aymestry; Trilobites and Acrocystella from the Shineton Shales; Foraminifera and other Fossils from the Thanet Sands, near Ramsgate; a selection of Ornamental Shells and Malayan Butterflies; and Micro-sections of "Flaser-Gabbro" from Scotland and Germany, of Diamantiferous "Blue Ground" from Kimberley, and of Chert with Organisms. A varied assortment of Microscopical Glass Slips and Covers always on hand.

JAMES R. GREGORY,

Mineralogist and Geologist.

SPECIAL AND TYPICAL COLLECTIONS FOR STUDENTS, LECTURERS, MUSEUMS, &c. EVERY REQUISITE FOR PRACTICAL WORK. ROCK SPECIMENS, AND ROCK SECTIONS FOR MICROSCOPIC EXAMINATION. THE LARGEST STOCK AND GREATEST VARIETY IN LONDON. NEW LISTS NOW READY.

New Catalogue of Mineral Specimens,

Arranged for the Selection of Single Specimens, &c., with Prices. Also New Lists of Rare Minerals, Rock Specimens, Geological Apparatus, Collections, Hammers, and Microscopic Sections of Rocks.

And may be had post free on application at the Repository and Museum,

88 CHARLOTTE STREET, FITZROY SQUARE, LONDON.

MICRO-PETROLOGY.

Rock Sections for the Microscope, of special value and interest:—Porphyritic Basalt, Lion's Haunch, Edinburgh; Dolerite with Porphyritic Augite, Crawford John, Lanarkshire; Perlitic Pitchstone, Saxony; Pikrite, Inchcolm, Firth of Forth; Thulite, Norway; Siliceous Oolite, Pennsylvania; a Siliceous Rock with a perfect oolitic structure.

1s. 6d. each; extra large Sections, 1s. 9d. and 2s.

Collections of Minerals and Rocks for Prospectors and Students.

CATALOGUES POST FREE.

Ready this Month.

SYNOPSIS DER HOEHEREN MATHEMATIK.

VON JOHANN G. HAGEN, S.J.,

Director der Sternwarte des Georgetown College, Washington, D.C.

The work is intended to present a general view of the higher mathematics. It may be regarded as exhibiting, like a terrestrial or a celestial chart, a network of co-ordinates, which show at a glance the discoveries made in mathematics up to the present day.

The work is not intended to serve as a text-book; nor is it a mere collection of formulas or tables. It is a book of reference, a kind of "Encyclopædia of the Higher Mathematics," in which the collected material is systematically arranged. While it sets the leading propositions prominently forward, the Synopsis merely indicates the deductions. It is a feature of the Synopsis entitling it to more than ordinary interest, that it takes notice here and there of the desiderata in the science of mathematics, indicating the points upon which the labour of future investigators may be most profitably employed.

The author has personally examined the whole literature of the science, including not only the works of all the great masters since the time of Euler, but also the articles in periodicals to which he makes reference. He has allowed no quotation to pass without verification, and, wherever found necessary, corrections have been made

The Work will be completed in 4 Volumes. Volume I. will be ready in August, Price 30s., and will contain—

Part I.: Theory of Numbers.—Part II.: Theory of Complex Quantities.—Part III.: Theory of Combinations.

Part IV.: Theory of Series.—Part V.: Theory of Infinite Products and Factorials.—Part VI.: Theory of Continued Fractions.—Part VII.: Theory of Finite Differences.

Part VIII.: Theory of Functions.—Part IX.: Theory of Determinants.—Part X.: Theory of Invariants.—Part XI.: Theory of Groups.

Part XII.: Theory of Equations.

SIMPLE BUT EFFECTIVE.

McLEOD'S SUNSHINE RECORDER.

This ingenious instrument, which is the invention of Prof. McLeod, F.R.S., of Cooper's Hill College, Staines, consists of a cylindrical metallic camera, opposite to the lens of which is a thin glass sphere silvered inside. The sphere is mounted on a slide provided with rack and pinion for focussing the image of the sun on the sensitised paper placed in the base. The instrument must be placed with its vertical plane in the meridian and inclined with the sphere upwards so that the axis of the camera makes an angle with the horizontal equal to the latitude of the place at which it is set up. The support is constructed to suit the latitude; the observer has merely to place the instrument in the meridian.

PRICE £6 15s.

THURSDAY, AUGUST 13, 1891.

THE INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

THIS Congress, the work of which we refer to in another column, which is now in full swing, promises to be one of the most important meetings of the kind that has ever been held, not only in point of numbers, but also on account of the far-reaching results likely to accrue from it.

A remarkable combination of circumstances has contributed to its success. In the first place, it is held in the country which has been the pioneer of sanitary work; and then it has the patronage of Her Majesty the Queen, who, it is well known, takes a deep personal interest in its success; and has as its President, not merely in an honorary sense, His Royal Highness the Prince of Wales, who presided and gave an admirable address of welcome at the splendid opening meeting on Monday in St. James's Hall.

This is the seventh of a series of similar Congresses which have been held in various parts of Europe, and one is tempted to ask what they have accomplished. An answer is at once forthcoming. The all-important question of quarantine has been discussed at several of these Congresses. Not to go farther back than the Congress at The Hague, held in 1884, we find, from the excellent reports issued by the editors of the *Lancet*, that then the feeling in Europe was so strongly opposed to the English views as to the inutility of quarantine and the superiority of our method of medical inspection, that the English delegate was not even allowed to explain the English position in the matter, but the discussion was peremptorily closed, on the ground that the subject had been sufficiently discussed on the previous day. At the Vienna Congress, in 1887, quarantine was again discussed under the subject of cholera; and the veteran Pettenkoffer told the members of various countries present that they had only to follow the example of England, in looking after their systems of water-supply and sewerage, and in isolating cases of infectious disease, and they would be no more afraid of cholera than the English were, even with their continual communication with India, the home of that disease, and would have no need of quarantine, with all its vexatious and ineffective restrictions, and all its unnecessary interference with commerce. Now, Continental opinion is almost entirely on our side, and it is doubtful whether there will be any serious discussion on the matter.

But there are many other subjects with which the Congress will interest itself, and about which such an interchange of views as can only be obtained at an International Congress must be of the greatest benefit. The whole subject of bacteriology has grown up within the last few years, and one of the most important and best attended Sections of the Congress is devoted to it, many of the highest authorities on this subject having been attracted here to take part in the discussion under the presidency of Sir Joseph Lister. The abnormal prevalence of diphtheria, not only in our own large towns, but also in those of other parts of Europe and in America, in many cities of which, especially in the Western States of North America, it has become a veritable plague, is likely to occasion an important discussion in Section I., under the presidency of Sir Joseph Fayrer. The mention of his name leads us to observe that India is well to the front in this Congress, for not only have a number of delegates been sent by her Provinces and Native States, but they have also largely contributed to the funds of the Congress.

Influenza, too, our new plague, about which we seem to know so little, might be discussed, as to its mode of spread and methods of prevention, with great advantage at a meeting where so much experience from all parts of the world is focussed.

An especial feature in this Congress is, as might be expected in England, the prominence which is given to engineering and architecture in connection with hygiene, there being two separate Sections devoted to these branches of the subject.

The division of demography, too, which has been so much talked about on account of its name, which was up to the present time unfamiliar to English ears, and which has been defined by some wag as "the art of drawing the public," has attracted, under the presidency of Mr. Francis Galton, many of the most eminent statisticians of Europe, whose discussions cannot fail to promote the attainment of more uniformity in the methods of statistical inquiries.

This is an age of Congresses, and if they are, as it is universally agreed that they are, of any use at all, it is self-evident that the most useful and the most important are the international ones.

A LIFE OF DARWIN.

Charles Darwin: His Life and Work. By Charles Frederick Holder. (New York and London: G. P. Putnam's Sons, 1891.)

BETWEEN the voluminous "Life and Letters" of his father, by Prof. Francis Darwin, and the brief epitome of Darwin's work, by Mr. G. T. Bettany, published in 1887 in the "Great Writers" series, there has hitherto been a gap which has only been partially filled by such books as Grant Allen's "Charles Darwin" in the series of "English Worthies." In the first of the works mentioned, our great naturalist is chiefly allowed to speak for himself, while in the second we have a digest of his scientific achievements. Although it has been generally considered that the life of Darwin from the time of the return of the *Beagle* was too uneventful to make an interesting biography, we have always been of opinion that there existed sufficient material for a popular "Life" of the very greatest interest provided that this material could be skilfully and judiciously worked up. The work under notice supplies this want, and American and English readers are now provided with a biography which is both entertaining and accurate.

Of course the material out of which Mr. Holder has woven his story is for the most part to be found in Darwin's own writings, or in the "Life and Letters," and readers who turn to the pages of this book with the hope of finding new matter may be disappointed. But the very circumstance that out of the familiar records of the

Digitized by Google

voyage of the *Beagle*, and the later writings of Darwin, the author has been enabled to construct such a very readable volume, is the best tribute to his skill.

The task which Mr. Holder took up was by no means an easy one; the difficulty which he had to confront did not arise from paucity of material, but from a superabundance of records, owing to the very complete account of his own travels and observations which Darwin has bequeathed to us. To extract the salient points from these records, and to dress them up in the writer's own language, was a labour requiring considerable literary ability. Mr. Holder has shown that he was well qualified for the undertaking, and it is refreshing—after the "Summary of the Darwinian Theory," and similar productions to which we have recently been treated in this country—to find that an American naturalist is able to write an account of Darwin and his work in language expressing his own ideas on the subject, instead of stringing together a lot of disconnected quotations from Darwin's writings. Not the least praiseworthy feature of the book is the comparatively small number of extracts from the writings of his hero; the author is wise enough to recognize the fact that most reading naturalists may be supposed to be familiar with the text of the "Naturalist's Voyage," the "Origin of Species," and other Darwinian classics.

The present volume is one of the "Leaders in Science" series, published by the firm of Putnam's Sons. The author says in the preface:—

"When the publishers proposed to me the subject of the present volume, a life of Charles Darwin for American and English readers, I was particularly gratified with the suggestion that the work should be adapted to young readers as well as old. It has always seemed to me that the life of Charles Darwin was one eminently fitted to be held up as an example to the youth of all lands. He stood as the central figure in the field of natural science in this century, and while it is yet too early to present his life with any approximation of its results upon the thought of the future, it is apparent to everyone that his influence upon the intellectual growth of the country, and upon biological science in particular, has been marked and epoch-making.

"In the preparation of the work I have not attempted an analytical dissertation upon Darwin's life-work, neither have I discussed his theories or their possible effect upon the scientific world, but have simply presented the story of his life, that of one of the greatest naturalists of the age; a life of singular purity; the life of a man who, in loftiness of purpose and the accomplishment of grand results, was the centre of observation in his time; revered and honoured, yet maligned and attacked as few have been."

Having thus defined his object, the author proceeds to narrate his story, beginning with the boy Darwin, passing on to his Cambridge career, and then leading us through the scenes of his wanderings as naturalist to the *Beagle*. The major portion of the volume (twelve out of the twenty chapters) is thus pleasantly filled up; all the little personal incidents which give colour to the individuality of the man are skilfully brought in, and here and there the author interposes observations of his own which help to throw light on the questions discussed and the facts recorded by Darwin. Having in view the taste of his younger readers, a number of full-page illustrations have been introduced, some being reproduced from Spry's "Voyage of the *Challenger*," others from Gosse's "Romance of Natural History," others from Brehm's "Natural History," from Figuier's works, and from the *Century Magazine*. Many of the illustrations are new, the frontispiece, representing Darwin in his garden with the squirrels running up him, being well worthy of notice.

The working period of Darwin's life from the return of the *Beagle* to his death is dealt with in three chapters, in the course of which the author relates the history of the "Origin of Species," and the impetus given to the publication of that work by the independent discovery of the principle of natural selection by "Alfred Russel Wallace, a young Welsh naturalist, who was then travelling in the Malay country." This incident is of course familiar to all, but as an old story retold by a transatlantic admirer of Darwin it reads even now with the charm of freshness. The later works are referred to in chronological order, and in a succeeding chapter we have a catalogue of the honours conferred upon Darwin during his life. The seventeenth chapter contains an account of the Darwin family, beginning with William Darwin, of Marton, near Gainsborough, in 1500, and concluding with Erasmus, elder brother of Charles Darwin, the friend of Carlyle, who was described by the latter in his "Reminiscences," and whose amiable character was more fully portrayed by Miss Julia Wedgwood in the *Spectator* in 1881. The latter description from the pen of Miss Wedgwood is given by Mr. Holder *in extenso*.

The narrative, as such, ends with the death of Darwin in 1882, and the reader will turn with renewed interest to the eighteenth and nineteenth chapters, containing Mr. Holder's account of the Darwinian theory. The principles of this theory are fairly well expounded, considering the small amount of space which has been devoted to them. Natural selection is illustrated by a happily chosen and original example from the animal kingdom, viz. the adaptive coloration of the fauna of the Sargasso Sea. Another illustration of the principle is drawn from the vegetable world, viz. the evolution of a hairy seed adapted for aërial transport. The questions of geological time and the palæontological evidences of organic evolution are also touched upon, and here we think the author might have used more judgment. The formation of the chalk, for example, is not quite satisfactorily given, and the statement that the chalk cliffs of Dover have been elevated "by some convulsion of nature" (p. 185) will jar upon the geological susceptibilities of his readers. In a work intended for popular reading it would also have been safer to avoid any estimate of the time required for the denudation of the Weald, the more especially as Darwin himself admitted the unsoundness of such estimates by omitting this section in the later editions of the "Origin." The ancestry of the horse, and Prof. Marsh's discovery of the *Odontornithes*, are well brought in in connection with the palæontological evidence. We may point out in passing that the diagram illustrating the evolution of the horse, which fronts p. 62, is referred to both on pp. 189 and 190 as "the accompanying diagram," which is obviously an oversight.

In tracing the history of pre-Darwinian evolution, the author mentions the views of Bonnet, the doctrines of

Digitized by Google

Thales and Anaxagoras, the speculations of Leibnitz, De Maillet, Wright, Lambert, Herschel, and La Place. Of Buffon he says :—

"Buffon was the naturalist of the day in the time of Louis XV. and Louis XVI.,—a period somewhat famous for the restrictions which were placed upon men, and the denunciations with which new and advanced ideas were received. Thus advanced thinkers found that their theories in many instances, instead of leading them on to fame, but opened the doors of the Bastile.

"It is not improbable that Buffon was in accord with the feeling of the time, as while his great discursive work—'Histoire Naturelle,' of 1749-88—fully outlines the theory of evolution, in which he was a believer, it is done in an ironical, partly satirical manner, so that he could, if attacked, retreat by claiming that it was a satire on the advanced scientific thought of the time; . . . he was ready to believe that from a single unit in the beginning might have descended all the various forms of existing animal and plant life. It is curious to note that this pioneer evolutionist suddenly corrects himself and says: 'But no; it is certain from revelation that every species was directly created by a separate fiat.' We may suspect that this secession from a position so broadly taken was forced upon the evolutionist. Perhaps the clergy gave him close and suggestive attention, and he was offered the choice between the Bastile, the Sorbonne, and apology to offended orthodoxy. Be this as it may, Buffon was one of the early delineators of the modern theory of evolution, and despite his peculiar attitude, history accords him this recognition."

The works of Wolff, of Goethe, Geoffroy St. Hilaire Oken, Pander, Von Baer, Schleiden and Schwann, Von Mohl and Max Schultze, Lord Monboddo and Erasmus Darwin, are all referred to in due order; and a well-bestowed paragraph of praise is given to Lamarck. Later writers, such as Robert Chambers, Von Humboldt, Owen, Asa Gray, Herbert Spencer, and Youmans, bring us down to the birth of modern Darwinism.

To English readers the last (twentieth, but erroneously headed eighteenth) chapter will be one of the most interesting. It is entitled "The Darwin Memorial," and contains a series of addresses by American men of science, delivered at a special memorial meeting of the Biological Society of Washington soon after the death of the illustrious naturalist in 1882. The address of Dr. Theodore Gill, of the Smithsonian Institution, is a masterpiece of eloquence, treating of "The Doctrine of Darwin," and contrasting the doctrines of special creation and evolution. The address by William Dall, of the United States National Museum, is equally eloquent, and treats of Darwin in the form of a biographical sketch. Dr. John Powell, the Director of the United States Geological Survey, follows with an admirable address on "Darwin's Contributions to Philosophy." We cannot refrain from transcribing some of his remarks :—

"But Darwin's investigations have not ended research or completed philosophy. He brought scientific men to the frontiers of truth, and showed them a path across the border. Yet more than this he did. He pointed out one of the fundamental methods of research. Before his time philosophers talked about deductive methods and inductive methods. Darwin has taught us that both are fruitless. . . . By inductive methods, men are to collect facts, unbiased by opinions or preconceived theories. They are to gather the facts, put them together, arrange and combine them to find higher and still higher generalizations. But there are facts and facts—facts with value, and facts without value. The indiscriminate gathering of facts leads to no important discoveries. Men might devote themselves to counting the leaves on the trees, the blades of grass in the meadows, the grains of sand on the sea-shore; they might weigh each one and measure each one, and go on collecting such facts until libraries were filled and the minds of men buried under their weight, and no addition would be made to philosophy thereby. There must be some method of selecting, some method of determining what facts are valuable and what facts are trivial. The fool *collects* facts; the wise man *selects* them. Amid the multiplicity of facts in the universe, how does the wise man choose for his use? The true scientific man walks not at random through the world, making notes of what he sees; he chooses some narrow field of investigation; . . . his investigations are always suggested by some hypothesis—some supposition of what he may discover. He may find that his hypothesis is wrong, and discover something else; but without an hypothesis he discovers nothing. . . . Working hypotheses are the instruments with which scientific men select facts. By them, reason and imagination are conjoined, and all the powers of the mind employed in research."

The succeeding address, by Dr. C. V. Riley, gives an account of Darwin's entomological work, and comprises a graphic description of the naturalist in his home, drawn from personal reminiscences of a visit to Down. Dr. Lester Ward follows with his address on "Darwin as a Botanist," in the course of which he discusses, among other points, the bearing of Darwin's researches on the power of movement in plants on the great question wrapped up in the expression "tendency to vary." Dr. Frank Baker contributes the next address, on the expression of the emotions, and in this we again meet with a spirited advocacy of the Darwinian method :—

"But not as a fact-gatherer do we find him greatest. Many others have struggled with ant-like toil to amass piles of facts, which, like the ant-heap, remain but sand after all. Darwin brings to his work an informing spirit, the genius of scientific hypothesis. Breathed upon by this spirit, the dry bones of fact come together 'bone to his bone,' the sinews and the flesh come upon them, they become alive and stand upon their feet, 'an exceeding great army.' He searches always for the principles which underlie the facts and make them possible, realizing that the *phenomena*, the things which are seen, are temporal and transitory; the things which are not seen, the cosmical forces which govern and control, are eternal."

A Darwinian bibliography, by Frederick W. True, the Librarian of the United States National Museum, and an appendix giving a list of Darwin's works, conclude a volume of which enough has been said to commend it to all readers, whether youthful or adult, and which we on this side of the Atlantic cannot but appreciate as a most inspiriting picture of the life and work of the man who, of all others, has helped to emblazon our country's fame on the scientific scroll of the nineteenth century.

R. MELDOLA.

PINES AND FIRS OF JAPAN.

Monographie der Abietineen des Japanischen Reiches. Bearbeitet von Dr. Heinrich Mayr. Mit 7 Colorirten Tafeln. (Munchen: M. Nieger'sche Universitäts Buchhandlung, 1890.)

FROM the time of Kaempfer and that of Thunberg to our own day, the Japanese Conifers have been the objects of special predilection on the part of botanists.

Digitized by Google

Zuccarini figured and described several that had been collected by Siebold, Lindley, Andrew Murray, Maximowicz, Franchet, and others, contributed greatly to the elucidation and delimitation of the several species. Robert Fortune, John Gould Veitch, and Charles Maries introduced many to our gardens. Horticulture has, indeed, rendered great service in this matter. The trees in question are valuable for ornamental purposes, and potentially as timber trees. The consequence of this is that collectors have accumulated specimens in large numbers and in different stages of growth. They have, moreover, supplied our nurserymen with seed, so that young plants are now numerous in our nurseries and plantations.

The study of the seedling plants, in their progress from the seed-bed towards maturity, has afforded valuable evidence concerning the morphology of the group and its probable genealogy, its filiation and classification. Cultivation has, for instance, shown that many of the very curious forms known under the name of Retinospora are, in reality, stages of growth of one, or at least of a few, species of Thuya, of Cupressus, or of Juniperus, so that the so-called genus is purely fictitious. In like manner *Abies bifida* and *Abies firma* have been proved to belong to one and the same species.

To fill up the gaps in our knowledge, and to correct errors arising from inadequate or imperfect material, it was necessary that the trees should be studied by a trained observer in the forests themselves. This was the more necessary as, to a large extent, our knowledge has been derived from plants cultivated by the Japanese and, in some cases, not a little distorted in the process. The earlier botanists had little or no opportunities of studying the native flora for themselves. Even Fortune was largely dependent on the Japanese nurserymen. John Veitch collected for himself on Fusi-yama, and Maries penetrated even to the forests of Yesso. Dr. Mayr, the latest writer on these plants, has enjoyed opportunities denied to his predecessors. After a distinguished career in Munich, Dr. Mayr proceeded to the United States, visiting the forests in all parts of the Union, and producing, as a result, a work which the best judges speak of in terms of high appreciation. Subsequently, our author visited Japan to organize the Forest Department, and fill the office of Professor of Forestry in the Imperial University of Tokio. In the execution of his duties Dr. Mayr travelled through the various provinces, and derived much information from the native foresters. One result is before us in the shape of a volume, printed in German at Tokio, and illustrated with seven coloured plates. The group specially studied by Dr. Mayr is remarkable for the relatively large number of endemic species. Thus, Dr. Mayr enumerates six species of Abies, all of which are peculiar to the Japanese islands. Five species of Picea are nearly as much restricted in geographical area. Tsuga, a genus represented in both the North-eastern and the North-western States of America, as well as in the Himalayas, has two species peculiar to Japan. The genus Larix, which also has a wide distribution in the northern hemisphere, has two species native to Japan, and not extending far beyond its limits. Six species of Pinus are enumerated by Dr. Mayr, and these also are almost exclusively Japanese, though some are found on the mainland adjoining.

The Japanese islands, then, form a centre of distribution of a group of species of a distinct character, differing markedly from a similar group of Chinese nativity, but approximating to the Californian and to the East American coniferous floras, and having representatives in other parts of Northern Asia and of Europe. The distinct character of the Japanese Coniferæ and their relationships are even more prominently brought into view when the other tribes of Conifers are considered. Dr. Mayr confines himself, however, to the Abietineæ, and we must here follow his example, in the hope that on another occasion we may be able to accompany him also through the other tribes.

In speaking of the distribution of these plants, Dr. Mayr alludes (1) to the tropical zone in which the genus Podocarpus is represented, but which does not specially concern us now; (2) to a sub-tropical zone in which are other two species of Podocarpus, as well as *Pinus Thunbergii*, which extends round the coast of all the islands, and less frequently *Pinus densiflora;* (3) a region of deciduous trees, such as chestnuts in the south or at the base of the mountains, or beeches and birches to the northward or at higher altitudes. Here grow especially the Cryptomeria, the various species of Chamæcyparis, Thuyopsis, and Sciadopitys. (4) The fourth zone, that of firs and spruces, occupies the high mountains in the centre of the island. Here are found *Abies Veitchii*, *Picea bicolor*, *P. Hondoensis*, and *Larix leptolepis*, which are peculiar to the main island, together with *A. Mariesi*, *A. sachalinensis*, *Picea ajanensis*, and *P. Glehni*, which extend northward, some even as far as the Sachalin and Kurile Islands. *Tsuga diversifolia* occurs from the region of the beech upwards to the Alpine zone. (5) The fifth, or Alpine region, also designated that of the Alpine pines, includes forms such as *Pinus pumila*, which is allied to the Swiss *P. Cembra*. We can only indicate these regions, as the discussion of their climatal features and plant population turns mainly upon plants different from those which form the staple of Dr. Mayr's present treatise.

Passing into detail, Dr. Mayr proceeds to describe each species separately, devoting much space to literary references, Japanese as well as European, and giving a description of the main peculiarities of the tree from an economic as well as from a botanical aspect.

A few new species are indicated, of the value of which we can hardly form a trustworthy opinion in the absence of authentic specimens. We venture, however, to doubt whether *Abies homolepis* is, as, however, others besides Dr. Mayr think, identical with *A. brachyphylla*. The leaf structure of the two is certainly different, and cultivation may yet reveal other differences. The names *bicolor*, *Alcockiana*, *ajanensis*, *jessoensis*, *japonica*, *microsperma*, as applied to one or more species of Picea, have been so variously understood by botanists, owing partly to accidental misplacement of labels, admixture of seeds, and to imperfect information, that it is very important to have an authoritative statement from such an observer as Dr. Mayr. If allowances be made for a large amount of variability within the conventional specific limitations, it

Digitized by Google

would seem from the figure as if Dr. Mayr's *Pinus pumila* might be referred to *P. Cembra*, whilst *P. pentaphylla* is obviously a near ally of the East American *P. strobus*.

Dr. Mayr's "diagnose," however, is really a rather diffuse description in German, not conveniently adapted for the comparison of one form with another. In this absence of concise comparisons in Latin, modern botanists, especially German ones, compare unfavourably with their predecessors. On the other hand, Dr. Mayr establishes some sectional characters which may prove useful, such as the three sections into which he divides the genus Picea, viz. Morinda, Casieta, and Omorica, the last, indeed, having been already proposed by Willkomm.

Hybrid forms between *Pinus Thunbergii* and *P. densiflora* are mentioned, as well as a whole series of garden varieties which have either originated in Japanese gardens or have occurred as "sports" on the wild trees, and which have been propagated by grafting by the Japanese gardeners. These are likely to prove of scientific interest, and will be specially interesting for garden purposes.

Seven quarto coloured lithographic plates accompany the volume, giving details of the foliage and cones. We could have wished that representations of the trees themselves could have been supplied, and that an alphabetical index of species and varieties had been added to the classified table of contents. When we have so much that is valuable and interesting presented to us, it may seem ungracious to hint at deficiencies, but really in this case to ask for more shows how greatly we appreciate what we have, and is about the greatest compliment we can pay to the author. MAXWELL T. MASTERS.

ELEMENTARY HYDROSTATICS.

Solutions of Examples in Elementary Hydrostatics. By W. H. Besant, Sc.D., F.R.S., Fellow of St. John's College, Cambridge. (Cambridge: Deighton, Bell, and Co., 1891.)

THIS is a collection of solutions, or a *crib*, to the author's well-known "Elementary Hydrostatics," which has held the ground in elementary instruction unchallenged since 1863.

It was cruel, though, as Dr. Besant apologetically explains, unavoidable, to keep the world of instructors waiting so long for these much-needed solutions and explanations of the questions in his Hydrostatics.

The Solutions are stated to be almost entirely drawn up by Mr. A. W. Flux, who has found it necessary to explain that the equation $p = g\rho z$ must be interpreted as giving the pressure p in *poundals per square foot* (or in C.G.S. *barads*, might well have been added); but he has not explained that the effect of this reverential interpretation is to make ρ and w signify the same thing; so that two symbols are used to denote the same quantity, although one, ρ, is called the *density*, and the other, w, the *intrinsic weight*.

But in 1863 the word *poundal* was not known, nor was any mode of measuring force and pressure in use, except in terms of gravitation units.

It would take too long to recount the despair of the instructor and the confusion of the student at the different modes of reconciliation of the equations $p = g\rho z$ and $p = wz$, variously used as measuring the pressure at a depth of z feet.

Because thirty and more years ago it was thought convenient in dynamical equations to replace Wg by a single letter M, merely for purposes of convenience in writing and printing, it was and is still taught in our theoretical treatises that the equation $W = Mg$ is the expression of a subtle and fundamental law of Nature, to be introduced even into a treatise on Elementary Hydrostatics, presumably taken up before a student has commenced Dynamics, and before he can understand what acceleration in general, and the particular acceleration g, can mean.

What must, for instance, be the feeling of Tommy Atkins, when the Musketry Instructor begins on p. 1 of the official "Treatise on Military Small Arms," 1888, with this definition of Mass, taken in a garbled form from chapter ii. of the Hydrostatics and elsewhere.

"Mass: The *quantity of matter* in any body, the sum of all the particles of the body; it is proportional to the weight, whatever be the figure, or whether the bulk or magnitude be great or small; for the weight is equal to the mass multiplied by the force of gravity, or $W = Mg$, and the letters M and W are usually employed to denote the *mass* and *weight* respectively."

In short, this definition amounts to saying that *mass* is something we denote by the letter M, while *weight* is something we denote by the letter W; but we must always remember that $W = Mg$, where g is something unexplained, even when we measure mass in pounds and weight also in pounds; so that if g appears in one place, it will cancel again somewhere else, and not affect the ultimate numerical result.

But if, according to former instructions, we calculate the pressure from the equation $p = g\rho z$, we must notice that ρ, the density as defined in chapter ii., "Elementary Hydrostatics," is the weight in pounds of one-gth part of a cubic foot of the liquid, or $g\rho$ is the weight in pounds of one cubic foot of the liquid, so that $g\rho$ and w now measure the same quantity.

The unfortunate instructor was formerly called upon to reconcile these opposing statements, that w is sometimes the same as ρ, and sometimes as $g\rho$; now, however, he can take refuge behind the definite statements of this authorized collection of solutions.

But what is most wanted is a mathematical Censorship, to go through our hydrostatical treatises, expunging all the g's.

As to the mere mathematical geometrical part of the solutions, this is doubtless carried out with true Cambridge elegance, of which Dr. Besant is so well known an exponent; a trifle however, in comparison with the difficulty of the interpretation of the units in some extraordinary questions relating to the equations $W = sV$ and $W = g\rho V$, questions at one time considered a valuable test of clear thinking on the part of the student.

We counsel everyone who values his peace of mind to procure a copy of these Solutions, if called upon to interpret and expound the numerical results of the original "Elementary Hydrostatics."

OUR BOOK SHELF.

Plane Trigonometry for the Use of Colleges and Schools. With numerous Examples. By I. Todhunter, F.R.S. Revised by R. W. Hogg. (London: Macmillan and Co., 1891.)

TODHUNTER'S "Trigonometry" is a very familiar friend of ours, and we have now before us a bundle of letters which we received from the author in 1861 and 1862, in reply to our criticisms and corrections of the early editions. The first edition swarmed with small *errata*, for the pointing out of which we received warm thanks. It was a good book for some years, on account of the excellent collection of problems, but of late it sadly wanted bringing up to date. Mr. Hogg has done his work well, but possibly he would have produced a better independent book. The first 200 pages have undergone very little change, and we have only noted here and there an interpolated article. Chapter xviii., "Miscellaneous Propositions," contains several novelties (as contrasted with the last edition we have of the original work), such as geometrical proofs of familiar formulæ and graphs of the trigonometrical functions. There are numerous important additions in chapters xxi.-xxiv., which bring this part of the work more *en rapport* with present day requirements, notably Schlömilch's resolution of sin θ into factors, and a too brief account of hyperbolic functions. The prime feature is the addition of a very great number of excellent recent exercises in all parts of the subject. The work forms a good school-book, and will meet the requirements of a large number of students.

Lessons in Astronomy By C. A. Young, Ph.D., LL.D. (Boston, U.S.A., and London: Ginn and Co., 1891.)

THIS is the third of a series of text-books recently prepared by Prof. Young for use in schools and colleges of different grades. The two previous ones have already been noticed in NATURE (vol. xxxix p. 386, and vol. xli. p. 485). The present work is described on the title page as "a brief introductory course without mathematics, for use in schools and seminaries." The three books have much in common, and each one has many good points. We cannot help feeling, however, that the steps between them are too small. Almost exactly the same ground is covered by each, and they differ chiefly in the amount of previous knowledge assumed. But the acquaintance with mathematics required for a thorough comprehension of the "General Astronomy" is by no means great, and even for the "Lessons" a certain knowledge of geometrical principles is essential. If we must needs have three books, the "General Astronomy" contains too little, and the "Lessons"—a book of some 350 pages—contains too much.

The chief variation calling for notice is in the portion dealing with uranography. This now forms chapter ii., and, with the aid of the maps, forms a fairly complete and easy guide to the constellations. The notes on the legendary mythology of the constellations, which have been added for the benefit of students not acquainted with classical literature, gives this chapter an additional interest.

The book is brought well up to date, and is a model of good printing.

Cosmical Evolution: a New Theory of the Mechanism of Nature. By Evan McLennan. (Chicago: Donohue, Henneberry, and Co., 1890.)

THE author states that the essential principle of the new theory is "that every known heavenly body is connected with its neighbouring heavenly bodies by means of real, material bonds, and that every phenomenon of the universe, without exception, is due solely to the action of bodies upon one another through, and by means of, these bonds which join them together" (p. 48).

Among the principal evidences in favour of the existence of this material planetary connection is that "we actually see them with the naked eye" in the zodiacal light and in the streamers of the solar corona.

The theory is of a very general nature, and includes not only cosmical but terrestrial phenomena, such as aërial and aqueous tides, terrestrial electricity and magnetism. The author is of opinion that "the greater tidal wave is due to the sun, and the lesser to the moon" (p. 291).

The conditions of prelunar and other races of mankind are also discussed (p. 360). The work consists of 399 pages. There is no index.

The Telescope: an Introduction to the Study of the Heavens. By J. W. Williams. (London: Swan Sonnenschein and Co., 1891.)

THE writer of this book is author of "British Fossils, and where to Seek Them," and "Land and Water Shells, &c." In his preface he quotes with approval the adage, "Ground your knowledge of any special group on a general knowledge of nature as a whole." This is perhaps why he now turns his attention from shells to astronomy. However this may be, the work has been carefully compiled, and is to be recommended as a safe guide. Some of the illustrations are excellent.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Silver Lodes and Salt Lakes.

SINCE the discovery, some five or six years ago, of the extraordinary Broken Hill lode of silver-bearing ores, the public excitement on the subject in this part of the world has been attended with comparatively little scientific interest in regard to the geological features of the argentiferous country and the probable origin of deposits so vast and so remarkable in character; yet I believe that an examination of the main topographical and geological features of the eastern parts of South Australia and the western parts of New South Wales will probably throw more light upon the interesting subject of the origin of argentiferous lodes than the study of any other now known part of the globe; and, as I have had an opportunity of going closely into the matter during a recent visit to Broken Hill, I propose to lay briefly before your readers a few facts which seem to afford presumptive evidence in favour of the supposition that salt lakes and silver lodes are causally connected.

An examination of the ores *in situ* at Broken Hill, and especially in the portions of the lode which are known as blocks 10 and 11, reveals the fact that stratification almost exactly similar to that of an ordinary alluvial deposit is practically universal throughout the lode. So obvious has this been from the very beginning of the working, that almost every mining man who has had anything to do with Broken Hill has remarked upon the very obvious fact that the ores are to be ascribed to an aqueous origin. The fissure in which the lode occurs varies from a few feet to seventy or eighty yards in width, and has almost vertical walls. Within these boundaries the stratified deposits of carbonates and chlorides are intermingled with immense bodies of kaolin and sulphides, with a considerable amount of an interesting silicate of zinc also carrying silver and lead. The Barrier District is one of the driest in the whole of this very dry continent, and there is no river within about seventy or eighty miles. The few intermittent watercourses which exist in the locality do not suggest anything but a dry and arid climate. In fact, the greatest difficulty now met by the mines and by the town of Broken Hill, which contains about 27,000 inhabitants, is the scarcity of water, and the doubtful nature of any catching grounds that have been suggested. If, therefore, water was the agency by which the deposits of

Digitized by Google

ore took place, it is evident that the conditions at the time must have been very different from what they are at present.

The key to the whole situation seems to lie in the fact, which has been so well pointed out by Mr. Alfred Russel Wallace and others, that the whole of the regions of Central Australia have emerged from the ocean at a period which, from a geological point of view, is comparatively recent. The axial lines of the watershed ranges appear to be rising at a more rapid rate than the neighbouring plains, and consequently some strange and interesting changes are taking place in the relations of the catchment areas of flood waters and their outlets. In the locality of Innamincka, almost due north from Broken Hill, there occurs a phenomenon which is obviously due to some such change of relations. The Strezlecki Creek runs to the south-west from Innamincka. Its bed holds immense deposits of drift-sand, and in the adjoining plains are to be seen many curious parallel ridges of sand-hills, all strongly suggestive of the action of drift water, such as at times passes across the surface of these vast interior plains at flood time. The Strezlecki Creek was apparently the outlet for most if not all of the water of Cooper's Creek at some period of time not at all remote. But at the present day it is only once in every four or five years that the stream runs at all. When a very high flood fills the bed of the Cooper to overflowing, the waters find their way over the low ridge of land which separates the present bed of the Cooper from that of the Strezlecki, and so on to Lakes Blanche and Gregory—those large salt evaporation pans which can scarcely with propriety be dignified with the name of lakes. The gradual elevation of the low ridge would appear to be the most probable explanation of this interesting phenomenon. Now, to the south of Broken Hill, and in the vicinity of the River Darling, there is to be found ample evidence of a somewhat similar occurrence. Vast accumulations of sand in parallel ridges are still to be seen crossing the plains, and a large river bed extends, from a place quite close to the junction of the Darling and Murray, northwards in the direction of Broken Hill. Whether this "Anabranch," as it is called, is really an old bed of the River Darling or not, I will not stay to inquire. It would, however, appear practically certain that some slight alteration in the level of the land has been responsible for the change in the direction of the flow of water.

The case is not an ordinary one of the diversion of a river owing to the accumulation of its own alluvium; and the sand ridges, which in places extend right down to the bed of the present river, suggest the action of water on a scale of magnitude very different from that which is at present to be seen. Here, then, we have both to the north and to the south of Broken Hill evidences of the existence in former times of floods of water, which at the present day are never at all to be seen on the southern side, and only once in every four or five years on the northern side. It is to be observed that both of these localities are within the line of country formed by the parallel mountain systems of the Flinders Range on one side and the Grey and Barrier Ranges on the other side. Between these two ridges the land slopes gradually to the west, and three salt lakes, of which the largest is Lake Frome, attest the fact that in all probability at one time vast quantities of sea-water were imprisoned by the rising of the land from the level of the ocean. But in South Australia these two ridges are joined by a band of high land, on which the present railway to Broken Hill has been laid. This band of country forms, along with the ranges at each side, a sort of *cul de sac*, from which at present the waters could have no escape to the southwards unless they rose to a higher level than is ever noticeable under existing conditions.

But this has not been the case in times gone by. The evidences of the action of water in the neighbourhood of the "Anabranch" make it to appear practically certain that at one time the flood waters, which swept through the salt lakes, must have poured over the ridge towards the River Darling, and found an outlet by that means. This, then, brings me to the most significant fact to which I wish to direct attention. The locality of Broken Hill is the lowest point in the axis of the line of country which forms what I have alluded to as the *cul de sac*. In the absence of any survey from which full data could be deduced, it is sufficient to take the levels of all the railway stations from the Flinders Range to Tarrawingie—a point forty-two miles north-east of Broken Hill. These show that the railway (which happens to follow the line of the ridge) dips gradually to Broken Hill, and then rises again towards Tarrawingie. The conclusion is therefore inevitable, from the data to which I have already referred, that Broken Hill is the locality at which the accumulations of flood-water from the great region of the salt lakes must have found their way across the connecting ridge and on towards the River Darling. I believe, if the localities of the silver lodes of Potosi and Comstock are examined, they will be found to bear somewhat the same relation to the extensive salt marshes south of Lake Titicaca, and to the salt, mud, and alkaline lakes respectively, that Broken Hill does to Lakes Frome, Blanche, and Gregory; but, in the case of the last-named, the time at which the action took place is apparently much more recent, and the evidences which it has left are, therefore, all the more evident. It is a significant fact that the whole of the horseshoe-shaped line of country, of which, as I have said, Broken Hill is the lowest point, is highly mineralized, and contains mines for gold, silver, copper, and lead; but of all these mines, the Broken Hill lode is really an epitome, containing, as it does, nearly every metal which is known to the practical miner, and some also of those which are more of scientific than of practical interest. In view of the existence, among other things, of large lateral shoots from this gigantic lode containing the largest specimens of native silver yet discovered in any part of the globe, it seems difficult to account for some of the phenomena present at Broken Hill without premising the agency of electro-deposition. Several of the arguments which were adduced by me in NATURE of March 20, 1890, in regard to the occurrence of gold, would appear to furnish equally strong presumptive evidence that earth-currents acting along the axis of the range have had something to do with the deposition of metals from their solutions during their passage across the ridge. My present purpose, however, goes no further than to call attention to the probable origin of the lode, which I believe is to be found in the minerals held in solution in the waters of some of the vast Australian lakes and evaporation pans.

GEORGE SUTHERLAND.

Adelaide, South Australia.

A Magnificent Meteor.

AT 1.15 a.m., on July 31, I observed a most magnificent meteor—a veritable Andromedes. It was much larger than Jupiter, which was on my right, in the constellation Pisces, shining to the best advantage on a dark blue sky. After the retina of my eye got clear of the dazzling light of the meteor, I turned to Jupiter, which was in a favourable condition for comparison, the clouds being opportunely absent, but it looked at least three times smaller than the meteor, which, indeed, was entitled to be called a fire-ball. It illuminated the whole district with the brilliancy of the noonday sun. I traced it back through Mira Ceti, and to the right of Mesartum Arietis, into the direction of λ Andromedæ. This magnificent meteor exploded near the earth, without any detonation. The light was perfectly white. There was a very peculiar feature in the apparition of this meteor: it appeared to be very near to me, and between its body and the horizon behind it there seemed to be a vast distance. In its explosion it assumed very large dimensions, and the effulgence lasted for three seconds with undiminished splendour. In reality there were two explosions. The trail of light was dim, except immediately behind, where it was thick and bright, but of short duration.

On the night of July 31, and on the morning of August 1, there was a brilliant display of stars for this time of the year; the Milky Way was well defined from horizon to horizon, denoting a certain degree of frost. At present, Jupiter is the most conspicuous and most brilliant ornament in the nocturnal heavens; here in Scotland its glory is enhanced by the somewhat frosty nights which occasionally visit us about this season.

DONALD CAMERON.

Paisley, August 3.

Bees and Honey-dew.

NEAR here is an avenue of alternate beech and oak trees, and, in walking through it, my attention has lately been drawn to a loud humming in the beeches, similar to that heard in lime trees when in flower, while the oaks are silent. The sound is, I find, produced from bees in search of the Aphis secretions on the leaves of the beeches, the under sides of which are sticky with the substance. The bees appear to be all of one type—a small size of the large humble-bee—with a white tail. They never settle on the under sides of the leaves direct, but just on the margins

Digitized by Google

and then creep underneath, when, after running about and exhausting the supply, they fly off to another leaf, exactly as if they were visiting flowers. The leaves of the oaks are clean, and have no "honey-dew" on them. F. M. BURTON.

Highfield, Gainsborough, August 5.

Dredging Products.

AMONGST the products of the dredgings which my friend the Rev. J. H. Crawford and I are procuring from the Voe here, I am glad to be able to record the presence of Actinotrocha. We only got two or three specimens at first, but to-day a large number was procured from the surface net. One or two have attained to the Phoronis condition since being brought in. They answer in all respects to *Actinotrocha branchiata*, but seem to be as a rule less pigmented than the specimen found in St. Andrews Bay.

Actinotrocha branchiata has now been found on both sides of Scotland and England, and also at Heligoland; but, besides being got in the North Sea and on the west coast of Britain (*vide* NATURE, vol. xxxiv.), it seems also to be found on the western side of the Atlantic, for Wilson records it from Chesapeake Bay. It is thus distinctly a northern form, but has a wider distribution than has hitherto been supposed.

Sullom, Northmavine, Shetland, August 4.

THE INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

NEVER before, perhaps, in the history of science has there been assembled together such a numerous gathering of eminent men of science of different nationalities, or representing so many countries, for the purpose of discussing scientific problems.

Although it is little to the national credit that the importance of international Conferences on Health was suggested by the Belgians and not by ourselves, the conditions we are under here must not be forgotten. All other civilized countries have strongly represented among their Ministers, and among administrators, men of knowledge and competence; and elsewhere such Congresses are treated as of national concern.

Here, even in the matter of health, such powerful and economical methods of obtaining and distributing knowledge, such as Congresses like the present afford, are absolutely ignored by the party politicians to whom we commit our national welfare.

There can be little doubt that most of the good which is certain to arise from the deliberations now going on must be ascribed to the Queen and Prince of Wales, who came forward as Patron and President of a Congress ignored, as we have said, by our party rulers. This has been pointed out by the *St. James's Gazette*:—"The Prince of Wales has rendered a not inconsiderable service to his country by good-naturedly pulling the Congress out of the fire, and rendering a partial success of what came near to being a sad *fiasco*. But for his complaisance in sacrificing his holiday in coming up to London to take the chair, no public personage would have been present to welcome the two or three thousand guests bidden to the metropolis, or to give attraction and dignity to the opening meeting. . . . There are three Ministers whose departments have relation to the subjects treated by the Congress: Mr. Ritchie, who is our *quasi* Minister of public health and relief; Mr. Chaplin, whose department deals with the hygiene and prevention of disease of animals; and Lord Cranbrook, who controls medical education. Not one of these Ministers was present yesterday. Not even the Registrar-General, the head of the department of vital statistics, or a representative of the Home Secretary, took part in yesterday's meeting. The Prince, however, saved the position."

The devoted and unpaid labours of many eminent men have, however, with this slight touch of national feeling in high quarters, already rendered the success of the Congress unparalleled, and it is really wonderful to see what they have done, in spite of the enormous difficulty of arranging for a large number of people in such a city as London. Even the facilities afforded by Burlington House and the University of London buildings do not include a hall large enough for an adequate reception room; at first, therefore, there were difficulties, largely owing to its absence. This will hardly be wondered at, when we state that the numbers enrolled already are about 3000, and that there are 40 delegates from the German Empire and 70 from India, only to give two instances.

In anticipation of the meeting, among other official documents too numerous to mention, was prepared a Hand-book to London, with special reference to the needs of the members. This is a volume of 250 pages, in French and English, with eight plates showing the position of hospitals, cemeteries, markets, and the like. This has been published by Messrs. Cassell. There is another volume of 233 pages, containing abstracts of the more important papers to be read. Nor have the English Committee been the only workers. We have "Denmark: its Medical Organization, Hygiene, and Demography," with numerous illustrations and maps, published in English by authority of the Danish Government in time for the International Congress. This has been published by Messrs. Churchill.

In spite of the abstentation of any notice on behalf of the Government, it is pleasant to note the way in which the Lord Mayor and the Corporation, the Royal Colleges of Physicians and Surgeons, and numerous other public bodies and private individuals have kept up the credit of the nation for hospitality. Among the *conversazioni* must be specially mentioned that at the Guildhall on Tuesday evening, when the Lord Mayor received the members of the Congress. It was a brilliant and impressive sight, enhanced by the uniforms of foreign officers, and the unfamiliar garbs of members of our own distant dependencies. The various social arrangements made by the organizing committee are recorded in a special pamphlet of fourteen pages.

The proceedings began on Monday by a meeting in St. James's Hall, presided over by the Prince of Wales. Sir Douglas Galton first presented the Report of the Permanent International Committee, and *inter alia* gave the following account of the general organization:—

"The work of the Congress has been arranged in two divisions, viz. hygiene and demography, and it has been found necessary to divide the former into nine sections, each under a separate president, and with separate organization. Committees have been organized in foreign countries to further the interests of the Congress in a more direct manner than could be done from England. Delegates have been appointed by all the Governments of Europe, and also by the United States, Mexico, Venezuela, Japan, Persia, Egypt, by the provinces and native states of the Empire of India, by the most important colonies, and also by numerous municipal authorities, universities, scientific and medical societies, and other institutions throughout the world, and large numbers of the most important authorities on the subjects to be treated of have sent communications to be laid before the Congress."

After the reading of this Report, the Prince of Wales opened the proceedings by a careful and sympathetic address. One part of it referred to the dangers to health inevitable to the conditions under which we live. He remarked in relation to these dangers:—

"It will be no trivial work if their sources and probable remedies can be clearly pointed out, and especially if this can be done, as in a Congress such as this it should be, in a strictly scientific manner, calmly and dispassionately, without any reference to either general or municipal politics, or for any other purpose than the promotion of health. It is only on conviction such as may thus be pro-

Digitized by Google

duced that the appointed sanitary authorities can compel the changes necessary to be made; for such changes are almost always inconvenient or injurious to some, and might even seem unjust to them, unless it be made quite clear that they would be very beneficial to the community. But my hope is that the work of this Congress may not be limited to the influence which it may exercise on sanitary authorities. It will have a still better influence if it will teach all people in all classes of society how much everyone may do for the improvement of the sanitary conditions among which he has to live. I say distinctly 'all classes,' for although the heaviest penalties of insanitary arrangements fall on the poor, who are themselves least able to prevent or bear them, yet no class is free from their dangers or sufficiently careful to avert them. Where could one find a family which has not in some of its members suffered from typhoid fever or diphtheria, or others of those illnesses which are especially called 'preventable diseases'? Where is there a family in which it might not be asked, 'If preventable, why not prevented?' I would add that the questions before the Congress, and in which all should take a personal interest, do not relate only to the prevention of death or of serious diseases, but to the maintenance of the conditions in which the greatest working power may be sustained."

The *Times*, in a leading article on the Prince's address, points out one very important practical matter in which we lag far behind many foreign countries, and which may serve as an excellent illustration of the Prince's words about inconvenience or apparent injustice to individuals. "The weak point of English sanitary law is in respect of regulations for the slaughter of animals. In London, for example, slaughterhouses are small private establishments, often situate up little alleys or courts, surrounded by dwelling-houses, and not only destitute of many conveniences which they should possess, but also affording great facilities for the slaughter of diseased animals, and for the distribution of their flesh as food. In many Continental cities public *abattoirs* have been established upon a large scale, and all private slaughtering is forbidden. At these *abattoirs* there is an abundance of space, of air, of light; there is an excellent water supply; and the slaughtering is conducted under the supervision of officials, governed by rules which not only protect cattle against unnecessary cruelty or ill-usage, but which provide for the systematic inspection of meat before it is permitted to be sold. We shall certainly hear a good deal, during the sitting of the Congress, as to the importance of preventing the consumption of the flesh of tuberculous animals; but this, however important it may be, can never be done while the innumerable small private slaughterhouses are suffered to remain."

At the conclusion of the Prince's address, speeches were delivered by representatives of France, Italy, Austria-Hungary, Saxony, and Prussia. It is pleasing to record that all bore high tribute to the part which has been played by England in the promotion of measures calculated to preserve and improve the public health. On this point, Dr. Brouardel (France) was indeed specially emphatic:—

"In the year 1837, the year of the coronation of Her Gracious Majesty, appeared the Act which rendered obligatory the registration of deaths. This Act inaugurated the era of administrative reforms concerning the public health which our valued colleague of the Local Government Board has rightly called 'the Victorian era.' This Act did not long remain alone. Under the impulse given by two of your most illustrious patriots, William Farr and Edwin Chadwick, you have organized a system of registration of the causes of diseases and of deaths. Certain important cities, before the law made it obligatory, obtained supplies of water beyond all suspicion of pollution, and adopted systems of removal of foul water and waste matters. In these cities, whose action cannot be too much praised, the sickness and death rates diminished rapidly; this furnished the necessary proof it was time for reform. Twenty years ago the Local Government Board was established, and in 1875 had submitted to Parliament a Bill for the protection of the public health. During its discussion in Parliament one of your greatest Ministers (Disraeli) pronounced in the House of Commons these memorable words, which should be repeated in all countries and in all Parliaments: 'The public health is the foundation on which repose the happiness of the people and the power of a country. The care of the public health is the first duty of a statesman.' Since this, each year you have made fresh improvements in your sanitary laws; if in your eyes they are not perfect, in the eyes of the nations who surround you they are an ideal towards which all their most ardent aspirations tend. It is your example they invoke when they claim from the public authorities the powers necessary to oppose epidemics, to combat the scourges which decimate their populations. You have taken the first rank in the art for formulating laws for the protection of health; this is not all that you have done in the domain of hygiene. Among the diseases which one can properly term pestilential, there are, thanks to the work of the hygienists of all countries, certain ones which from the present time may be considered as preventable: such are small-pox, typhoid fever, dysentery, and cholera. For one of these, the most terrible, the immunity conferred by vaccination is absolute. The person upon whom this immunity is conferred can pass through the most severe epidemics, and expose himself to all sources of contagion without being affected. Who is it who thus preserves from death, from blindness, from infirmity, millions of human beings of all countries and of all races? On May 18, 1796, a date which might well be the date of a great battle, Jenner inoculated with vaccine matter by means of two superficial incisions, the youth James Phipps. Protection against small-pox belongs to you; the world will be to you for ever obliged. Let us consider two other epidemic diseases. Is it possible to establish the conditions of propagation of typhoid fever without quoting the names of Budd or of Murchison? I am aware that in 1855 Dr. Michel de Chaumont had for the town in which he lived experimentally established the *rôle* played by drinking-water in the propagation of this disease. Unhappily, public opinion was not prepared, and his discovery was not listened to. In the work which we are considering, the efforts of the English school were most fruitful. May I recall the fact that it was the epidemic of cholera in 1866 in England, which gave birth to the theory of its propagation by drinking-water? Was it not at that date that, under the influence of your hygienists, the Lords of the Privy Council issued an order formulating the laws of prevention which we adopt to-day? Certain it is that even in England these discoveries have not immediately borne all their fruit. The anti-vaccination leagues are not yet dead. Proofs accumulated during a century have not sufficed to cure that mental blindness which is congenial. . . . Can France be represented in a Congress of Hygiene without recalling the name of M. Pasteur? For centuries we have asserted that epidemic diseases were propagated by means of contact, by the air, by the effluvia, by miasmata. The idea of morbific germs, if not the name, is even found in the works of Hippocrates, but in what an uncertain sense. The theory of contagion has passed from century to century with strange modifications; the uncertainty of the methods of research and the difficulties of observation bound up together truth and error. It remained for Pasteur to prove the existence of these germs, their form, their life, their mode of action, and by their attenuation to solve the problem of immunity. Thanks to his work, and thanks to those of his pupils, realities have succeeded to contingent possibilities. We know some of our enemies,

Digitized by Google

their habits, and their mode of penetrating the body ; up to this time man was conquered by these infinitesimal beings, but, thanks to recent discoveries, he will be their conqueror. When, at the beginning of a century, one can inscribe the name of Jenner, and at its end that of Pasteur, the human race may rejoice. More has been done for it against misery, disease, and death than in any one of the centuries which have preceded it. You, gentlemen, you have been the initiators; this title will never be disputed with you. When a great people has given such an example ; when, by her gracious patronage, Her Majesty the Queen, and when, by his presence, His Royal Highness the Prince of Wales, testify that for them this era of reforms is not closed, it is only right that those who try to imitate them, and to give their country similar institutions, should come to bring to that people, and to their Sovereign, the homage of their profound respect."

Dr. Van Coler, the Medical Director-General of the Prussian Army, the representative of the German Government, followed suit, and showed the aid rendered to armies by the improvements in sanitary science. We give the following short extracts from his speech :—

"It is indeed with a feeling of joyous pride that from this place and in this country, where we have to trace the very cradle of all modern science of public health, I am permitted to point out how the many efforts made in the direction of hygiene radiating from England were, especially in Germany, hailed with much delight ; where they received the most careful attention, and where they ever since have been most actively promoted. . . . If from our army, diseases like malaria, small-pox, dysentery, have completely, or almost completely, disappeared ; if typhus fever and diphtheria become more and more diseases of the past, we have to be thankful for these attainments to the development and application of hygiene. . . . It is now an established fact that infectious diseases are by no means a necessary evil in the army. They are simply diseases which can be avoided, which can be powerfully opposed, and against which the science of our days battles victoriously with ever-increasing success."

Dr. Körösi's address will be welcome to many, as he exactly defined demography—which is a puzzle to many outsiders—and pointed out the early work done by members of the Royal Society :—

"This branch of science, the very nucleus of statistical work, which, in fact, is quite a science in its own right, has chosen the task to investigate the laws which regulate the life, increase, and decrease of nations. Its work, therefore, comprises three main parts: statistics of natality, of mortality (this part including biometry, the science of measuring the duration of human life), and of the increase of population. And when inquiring now who were the founders of this new science, we shall hear unanimously quoted the names of England's sons—Graunt, Petty, Halley, Malthus. Gentlemen, to-morrow, when we are to begin our work, we shall meet within the venerable hall of the Royal Society. The representatives of demography must feel a deep emotion when entering those rooms, which are so intimately connected with the history of their science, for this is the place where, 220 years ago, demography was created. It was in those halls, in their very first youth then, but soon conspicuous to the whole world by the genius of Newton, that appeared the work of Graunt which forms the starting-point of demography ; and here the King himself, admirably appreciating the work done, recommended the author to be received as a member of the learned Society. It was there that shortly afterwards Sir William Petty, by his eminent power, raised the new science to political importance and to popularity, and in the same place, again, in 1693, the famous Halley became the founder of the most important part of demography, of biometry, by working out the first table of mortality. And now the young science, which two centuries ago left those halls shy and even without a name, has found its way over the whole globe. Having been worked out in Germany, having received a name and new ideas in France, and having been enlarged and imbued with a more scientific character by Quetelet, having got its well-equipped office in every country of the civilized world, we are proud to see now its numerous representatives meet at the same place where two centuries ago this science was born. After a triumphant career of 220 years, it returns to its home, to the old rooms in which it awoke to light, and again the Throne of England receives it with favour and benevolent interest. For demography not less than for all statistical work, it is of the highest importance that its representatives, scattered as they are over the whole globe, should fully understand each other, for only so we can accomplish our aim, that our observations comprise equally all countries of the world, that our researches are conducted and worked out on the same principles everywhere, and that we may unite the incomplete and often discrepant descriptions of the single nations to a full descriptive history of the whole of civilized mankind. This great aim fully deserves the praise the illustrious Prince Consort bestowed upon it from this very place thirty years ago. He said, 'The importance of the Congresses cannot be over-rated ; they not only awaken public attention to the value of these pursuits, bring together men of all countries who devote their lives to them, and who are thus enabled to exchange their thoughts and varied experiences, but they pave the way to an agreement among different Governments and nations to follow up these common inquiries in a common spirit by a common method and for a common end.'"

The meeting was subsequently addressed by Sir James Paget, Dr. G. Buchanan (of the Local Government Board), and others.

The Sectional work of the Congress began on Tuesday. The Divisions and Sections are as follow :—

Division I.—Section 1. Preventive Medicine. President, Sir Joseph Fayrer, K.C.S.I.—Section 2. Bacteriology. President, Sir Joseph Lister, Bart.—Section 3. The Relation of the Diseases of Animals to those of Man. —Section 4. Infancy, Childhood, and School Life.—Section 5. Chemistry and Physics in Relation to Hygiene. President, Sir Henry Roscoe, M.P.—Section 6. Architecture in Relation to Hygiene. President, Sir Arthur W. Blomfield, A.R.A.—Section 7. Engineering in Relation to Hygiene. President, Sir John Coode, K.C.M.G.—Section 8. Naval and Military Hygiene. President, Lord Wantage, K.C.B., V.C.—Section 9. State Hygiene. President, Lord Basing.

Division II.—Demography. President, Mr. Francis Galton.

We shall endeavour next week to give an idea of the results of the many important discussions which may be anticipated, but it is already clear that it will be impossible for us to give anything like a full report, for the programme of work to be gone through is enormous. The addresses of the various presidents on the opening day were in themselves important communications, and well fitted to give tone to the subsequent discussions.

PROGRAMME OF TECHNOLOGICAL EXAMINATIONS.

A SIGN of the general advance in technical education is shown in the new Programme of Technological Examinations just published by the City and Guilds of London Institute. The Programme contains 37 pages of additional matter, and the number of different subjects of examination has now reached sixty. The Council appear to be genuinely desirous of adapting the examinations to the conditions of the more important trades as practised in the principal centres of industry. To this end, many

Digitized by Google

of the sixty subjects are divided into different sections, corresponding to the separate branches of the same trade, or to the practice of the trade in separate localities.

In the new Programme we notice many important additions. A practical test, which is the surest preventive of cram, and excludes those who are not engaged in the trade from presenting themselves for examination, has been added to the syllabus of nearly all the subjects. Thus, next year, for the first time, there will be practical examinations in such widely different subjects as photography and boot and shoe manufacture. In many subjects dealing largely with the practical applications of science the syllabus has been entirely re-written. This is the case with "Electrical Engineering," which is now divided into two main subjects—"Telegraphy" and "The Transmission of Power"—the former being again subdivided, in the honours grade, into "Telegraphy" and "Telephony," and the latter into "Electrical Instruments," "Electric Lighting," and "Dynamos, Motors, &c." The subject of "Mechanical Engineering" is similarly divided into different sections. The Programme has been increased by the addition of a syllabus of instruction in "Goldsmiths' Work," in which subject a large class has been already established in Birmingham, and of a syllabus in "Ship Carpentry and Joinery," which is intended to meet the requirements of artisans engaged in the different shipbuilding yards throughout the country.

The continuous increase in the number of candidates for these examinations, and in the number of students receiving instruction in the different centres throughout the country, shows that there is a genuine demand among artisans for practical and concrete instruction dealing, in the first place, with the facts with which they are familiar in their every-day work, and, afterwards, with the scientific principles explanatory of those facts. From the table found on p. 17 of the Programme, it appears that this year 7322 candidates presented themselves, as against 6667 in the previous year, and that the number of students under instruction increased from 12,022 to 13,202.

The memorandum issued to County Councils, to which we have already referred in these columns, is re-published in the Programme. It draws the attention of County and Borough Councils to the fact that, after the examination in May 1892, the grants hitherto paid on the results of the examination will be withdrawn, and that a substantial portion of the funds thus set free will be devoted to the improvement of the machinery of the examinations. Indications of the direction in which these improvements will be made will be found in the new Programme. It is important that the managers of technical classes should fully understand that, in future, the maintenance of such classes will depend entirely on local support. The large sums placed at the disposal of County Councils clearly render it no longer necessary that the City Guilds Institute should continue to make grants on results, which, although amounting in the aggregate to a large sum of money, proved to be quite inadequate to properly support the classes. It is, however, to be feared that the grant-earning tendency of the teachers and managers of local schools may cause the distinctly technological subjects of instruction to be neglected for the sake of science subjects by which grants may still be obtained from South Kensington. To prevent this, it is necessary that County Councils should realize the full importance of the work which Parliament has thrown upon them, and should recognize that in future they will be the authorities responsible for the conduct of the technical and, indeed, the secondary education also of the county. In the competition for money grants, technical subjects will be placed at a distinct disadvantage as compared with ordinary science subjects, and it is the more necessary, therefore, that the teaching of these subjects should receive adequate support from local authorities.

In order that the teaching in different localities may be duly adapted to the trades practised in those localities, and may be regulated by these requirements, and not by the grant-earning capacity of the subjects of instruction, it is very desirable that County Councils should organize, independently, or in connection with the City Guilds Institute, a system of inspection of local classes. The value of examinations is immeasurably increased when they are supplemented by inspection by competent experts, and it is to be hoped that some system of inspection of technical schools, which shall include the methods of instruction adopted, will soon be organized.

The Institute's Programme offers to different localities a wide choice of trade subjects, ranging from simple handicrafts to industries involving some of the most difficult applications of physical and chemical science. To the syllabus of each subject is added a valuable list of works of reference, which forms by itself a very complete guide to books in technology. The list of examiners, many of whom have this year been newly appointed, includes well-known experts in each branch of trade, and is a guarantee of the efficiency of the examinations. The future development of technical education is now very largely under the control of County Councils. They possess the funds without which no real progress can be made. But, besides funds, experience and organization are needed, and there can be no doubt that the members of County and Borough Councils will derive much valuable information, and many serviceable suggestions, from the new edition of the City Guilds Institute's Programme of Technological Examinations.

BOTANICAL SURVEY OF INDIA.

THE organization of a Botanical Survey of India, which has been under consideration since 1885, has been finally settled by the following resolution of the Government of India, dated Calcutta, February 26, 1891:—

(1) The scheme for carrying out the botanical survey of India, which has been under consideration for some time, was finally completed a year ago, and His Excellency the Governor-General in Council considers that it is now desirable to publish the details for the general information of local Governments and Administrations.

(2) In February 1885, Mr. Thiselton Dyer, Director of the Royal Gardens at Kew, prepared for the Government of Madras a Memorandum on the constitution of a Botanical Department for the Madras Presidency, one result of which was the eventual establishment of a Botanical Department for that Presidency. In sanctioning the Madras Department, the Secretary of State for India took the opportunity to suggest for the consideration of the Government of India whether, without interfering with the control exercised by the Provincial Governments, it would not be possible to bring into communication the various Botanical Departments of the different Provinces, the desirability of such an association having been prominently noticed by Mr. Thiselton Dyer in his Memorandum of February 1885. The wider scheme thus suggested by the Secretary of State was accordingly considered; and the first step taken for the organization of a Botanical Survey for all India, which was to have its centre in the Royal Botanical Gardens at Seebpur, Calcutta, was the transfer from the control of the Government of the North-Western Provinces and Oudh, to that of the Government of India, of the Superintendent of the Botanical Gardens at Saharanpur. This measure was demanded by the need for botanical survey in the Punjab, Rajputana, Central India, and the Central Provinces, which had hitherto been unrepresented by any

Digitized by Google

botanical officer, as well as by the necessity for having a botanical officer at the disposal of the Government of India to accompany military expeditions beyond the frontier.

Arrangements were then made, with the concurrence of the local Governments concerned, under which the following territorial division of India was prescribed for the purposes of botanical survey:—

Under the Superintendent, Royal Botanical Gardens, Calcutta.—The Provinces of Bengal, Assam, and Burma, the Andamans and Nicobars, North-East Frontier Expeditions.

Under the Government Botanist, Madras.—The Presidency of Madras, the State of Hyderabad, the State of Mysore.

Under the Principal, College of Science, Poona.—The Presidency of Bombay, including Sind.

Under the Director, Botanical Department, Northern India.—The North-Western Provinces and Oudh, the Punjab, the Central Provinces, Central India, Rajputana, North-West Frontier Expeditions.

The distribution above stated was reported to Her Majesty's Secretary of State, and his Lordship has been pleased to express his satisfaction with these arrangements.

(3) The Government of India now desire to communicate the following observations as to the central position which, in conformity with the suggestions of the Director of the Royal Botanical Gardens at Kew, the officer at Seebpur will occupy in the scheme for the botanical survey of India, and as to the sphere and nature of duties of each botanical officer, so far as they are connected with botanical survey.

It is desirable that the Seebpur Institution—which, as remarked by Mr. Thiselton Dyer, "though technically Provincial, must, at any rate in external estimation, from its age (it has passed its centenary), from its scientific traditions, and from the splendour of its maintenance, rank as Imperial"—should, without any interference with the Provincial control over the Royal Botanical Gardens, be officially recognized as the acknowledged centre of the Botanical Survey of India, and that to it should be referred the solution of all problems rising out of the practical or scientific study of Indian botany. In view of the important position which the Superintendent of the Royal Botanical Gardens, Calcutta, will thus occupy as the central authority in the Botanical Survey of India, the Government of India have, with the concurrence of the Secretary of State, added to Dr. King's present designation the official title of "Director of the Botanical Survey of India," and it is requested that in all correspondence dealing with subjects relating to general botanical exploration the latter title should be employed. The more effective botanical survey of Burma and Assam has also been intrusted to the Director, who will arrange a definite programme each year for the purpose in communication with the Chief Commissioners of those Provinces. He will also submit a separate Annual Report on the botanical exploration and researches effected during the year. The Government of India record with satisfaction that the local Administrations of Burma and Assam have each contributed an annual grant from Provincial revenues as an addition to the Imperial grant for the botanical survey of their provinces.

The investigation of the flora of the Madras Presidency and of the Hyderabad and Mysore States has been intrusted to Mr. M. A. Lawson, the Government Botanist and Director of Cinchona Plantations, who has expressed his opinion that the whole survey of the territories in question might, if diligently prosecuted, be completed in three or four years.

In Bombay, a scheme involving an annual expenditure of Rs. 4500 per annum on botanical work has been sanctioned, and Dr. Cooke, Principal of the College of Science, Poona, is officially recognized as in charge of botanical research in that Presidency. A herbarium exists at the College of Science, and a botanical collection is in course of formation at the Victoria Gardens, Bombay. The former place is to be the head-quarters of botanical research and collections, and the existing herbarium there is to be developed.

By the transfer of the services of the Superintendent of the Government Botanical Gardens, Saharanpur—who now bears the designation of Director of the Botanical Department, Northern India—the services of this officer are, as already explained, available for scientific investigation in all Provinces and States in Northern and Central India, as well as on expeditions beyond the north-west frontier. Mr. Duthie, the officer now holding the appointment, was thus in 1888, by his deputation to accompany the Black Mountain Expedition, enabled to acquire information concerning the flora of a country which had not hitherto been botanically explored. During the last three years, Mr. Duthie has also been deputed to Simla in the hot weather to assist in the preparation of the "Dictionary of the Economic Products of India," and during the same period he has been engaged in the botanical exploration of Rajputana and of the Central Provinces.

M. FAYE'S THEORY OF CYCLONES.

IN his admirable work on "The Principles of Science," the late Prof. Jevons thus sums up the characteristic mental attributes of the great scientific discoverer:—

"He must be fertile in theories and hypotheses, and yet full of facts and precise results of experience. He must entertain the feeblest analogies and the merest guesses at truth, and yet he must hold them as worthless till they are verified in experiment. Where there are any grounds of probability, he must hold tenaciously to an old opinion, and yet he must be prepared at any moment to relinquish it when a single clearly contradictory fact is encountered."

In his theory of cyclones, M. Faye has abundantly proved himself to possess those attributes that are defined in the first phrase of each of these sentences, and particularly the final one. Whether, however, in his treatment of this subject, the manifestation of the remaining and qualifying attributes is equally recognizable; whether he has fairly grasped and duly weighed all the established facts that are relevant and even essential to his hypothesis; and whether, among those that he has overlooked, there are not some that are "clearly contradictory" to the requirements of his theory, and therefore fatal to it—these are the questions that I propose to inquire into in the present article.

A true theory of cyclonic storms has not merely a scientific interest, it has also practical bearings of very high importance. When a ship is involved in the outer circle of a tropical cyclone, the vital problem which the seaman has to solve is, how to escape the fearful squalls of the inner vortex and the tremendous cross-seas of the central calm. In order to do this he must be able to judge of the bearing of the storm-centre from the actual position of his ship, and, to determine this point with even approximate accuracy, his sole guide is the direction of the wind. It may well be, then, that the safety of his ship, his own life and those of his fellow-seamen, are involved in the right answering of this question, "Does the storm-centre bear at right angles to the local direction of the wind, or is it from two to four points in advance of this position?" M. Faye's theory assumes and inculcates the former; the latter is consistent only with the hypothesis of an indraught from all sides, and an ascending current over the storm, the existence of which M. Faye persistently denies.

M. Faye's views on the nature of cyclonic storms are

Digitized by Google

too well known to render necessary any detailed description of them. An account given by Mr. Archibald in vol. xxxviii. of this journal (p. 149) is quoted without disapproval by M. Faye in his latest publication in the *Comptes rendus*, and may therefore be accepted as just. Its essential points are that cyclones are generated as great eddies in the higher regions of the atmosphere, and that there is a downrush of air in the vortex. "Dans ces tourbillons, tout semblables à ceux qui se forment dans les cours d'eau, les spires, d'abord très larges, iront en se rétrécissant par en bas, et leur girations progressivement accélérées, en vertu d'une loi bien connue de mécanique, amènent au contact du sol, et y concentrent sous une aire bien plus étroite que celle de leur embouchure les énergies continuellement renouvellées du fleuve aérien jusqu'à ce que son élargissement croissant aboutisse à la décomposition du cyclone."

Further on, with respect to the descending current in the vortex, he remarks: "L'air envoyé en bas sera en petite quantité mais animé d'une vitesse de rotation énorme."

I leave aside for the present any criticism of the physical and mechanical actions which M. Faye conceives to take place in these unfortunately inaccessible vortices of the higher atmosphere, and which I, for one, am unable to reconcile either with the results of direct observation or with well-established physical laws. For the moment I wish to concentrate attention on the question of fact, whether there is an indraught of air to the cyclone vortex at the earth's surface, and therefore necessarily an ascending current over it, or, on the contrary, an outflow from a descending current. This is the crucial point of the controversy, and by the answer M. Faye's theory must stand or fall. Indeed, M. Faye seems to recognize this, since he says:—

"L'argument le plus solide, celui qu'on m'opposait toujours pour prouver que l'air était ascendant dans les cyclones, à savoir le fait que les isobares étaient partout et toujours coupés sous un angle assez notable par les flèches des vents, de manière à accuser une tendance nettement centripète, &c."

He admits, too, that in certain cases there is really an indraught and ascent of air; only, on his view, these are not cyclones.

In order to forestall any objection on this score, I will take as the subject of inquiry the cyclones of the Bay of Bengal, the typical cyclones to which Mr. Piddington first applied the name, however etymologically incorrect. I trust, by this restriction, to escape ignominious dismissal from court on the plea that my witnesses are impostors —merely "prétendus cyclones"—and that their evidence is consequently irrelevant.

My first experience of a great tropical cyclone was the memorable storm that devastated the port and city of Calcutta on October 5, 1864. Up to that time, my acquaintance with cyclones was, like M. Faye's, "academic"; and under the impression that Reid's and Piddington's description of the winds, as blowing in circles or at right angles to the radius vector of the vortex, was an established scientific fact, on the evening of that day I sketched out, for the information of some friends, the probable course of the storm that was then passing away, having swept the port of its shipping, and left half the houses around us more or less wrecks. Having no other guide at the moment than the changing directions of the hurricane as experienced at Calcutta, on the supposition that the centre lay at right angles to these directions, I inferred that the storm had reached us from the north-east corner of the bay, and had followed a north-west or west-north-west course past Calcutta. What was my surprise, then, when accounts began to come in from other places in Bengal, showing that the course of the storm had been almost due north; and when, further, on plotting down the wind directions reported from other stations according to the hours at which they had been observed, I found that, instead of being at right angles to the radius vector, they were strongly inclined inwards; and such as, after making all allowances for their being only estimated directions and perhaps, therefore, a point or two in error, could be reconciled only with a sharp spiral indraught to and up to the central calm. Later on, when I obtained copies of the logs of ships that had been involved in the storm in its passage up the bay, I found that their wind observations, equally, were compatible only with spiral directions. Unlike M. Faye, I had no theory to support, and I submissively accepted the teaching of the evidence which lay so plainly before me.

This evidence is set forth on Plates I. and II. of the Report drawn up by Colonel Gastrell and myself, which was widely distributed at the time to scientific bodies, so that, in all probability, a copy must exist in the library of the Académie des Sciences.

Since then, many other storms in the Bay of Bengal have been carefully investigated, and their full details embodied in Reports drawn up by Messrs. Wilson, Eliot, Pedler, and myself. Without a single exception, the evidence thus accumulated has been to the same effect as that of the cyclone of 1864, and these gentlemen have all arrived at conclusions similar to mine. Thus, Mr. Wilson says[1]:—"The following rule may be used to determine the approximate bearing of the centre with as much accuracy as it seems to be possible to arrive at: *In the northern hemisphere, with the face to the wind, the direction of the centre is from ten to eleven points to the right-hand side*"; and, to quote only one of Mr. Eliot's numerous references to this subject,[2] "The air is drawn into the centre [of a cyclone], but is not drawn directly to it. The particles move by a kind of spiral path to the centre." And he gives a diagram, followed by charts of the Balasore cyclone of May 1886 and the Madras cyclone of November of the same year, as illustrative examples. And Mr. Pedler, in summing up the evidence of the False Point cyclone of September 1885, says[3]:—

"It is therefore clear, from these autographic records, that there was a very strong indraught towards the storm-centre, and that for a considerable portion of the time, even when the storm-centre was comparatively close to Hazaribagh, the winds were part of a well-defined spiral system. In fact, for a large part of the time they subtended an angle of less than 45° with the radius of the storm. . . . The records of five anemographs within the influence of the storm . . . show that the theory of the circular movement of winds in a cyclone, which was advanced by Reid and Piddington, and has been supported by some later writers, is utterly untenable. At considerable distances from the storm-centre the winds approach more to the radial direction of indraught towards the centre, as advocated by Espy, than to any circular movement. As the centre of the storm is approached, the circulation appears to become more defined; but even just outside the storm-centre there is no evidence to show that the direction is tangential."

The reports here quoted and many others, all leading to the same conclusions, have been communicated officially to a large number of scientific bodies in Europe and elsewhere, and taken together they probably furnish the most copious and complete body of existing evidence relative to the cyclones of a tropical sea. Not long since I examined the whole of the charts given in these reports, in order to verify Mr. Wilson's rule (quoted above) for ascertaining the bearing of the storm-centre when the

Digitized by Google

local wind direction is the only datum available, and I found that in the north of the Bay of Bengal, as the mean result of 132 measurements, the angle included between the wind arrow and the radius vector of the vortex was 122° (or 32° greater than a right angle), and that of twelve positions within 50 miles of the storm-centre, that is to say, in the inner circle of the hurricane, 123°. In the south of the bay it was 7° greater. Prof. Loomis, taking into account the land as well as the marine observations, and all barometric depressions, whether storms or otherwise, obtained an angle 25° greater, and differing only by 33° from the radial direction. It is hardly necessary to refer to Prof. Loomis's results of his examination of the Manilla cyclone of October 1882, which gave an angle of 118°, or to Mr. Meldrum's work on the cyclones of the South Indian Ocean, which has already been quoted by Mr. Archibald in his article in NATURE, mentioned above. All testify uniformly and in the strongest manner to the sharp spiral indraught of the winds in tropical cyclones, so that, as Prof. Loomis has truly remarked, "we thus see that tropical storms are spouts and not cyclones, and it is unfortunate that the term cyclone should have been ever adopted." In this view I fully agree, and I make M. Faye a present of the admission, that in an etymological sense, if in no other, Mr. Piddington's typical cyclones are not cyclones at all.

With all these results of a quarter of a century's experience present to my mind, when a gentleman holding the high position of M. Faye reiterates the assertion that the winds of tropical cyclones blow in circles, and that if ever they are found to blow spirally inwards such instances are not true cyclones (in the ordinarily accepted, *i.e.* denotative, meaning of the term), the impression I receive is somewhat such as M. Faye would probably experience were some equally eminent scientific authority to assert in his presence that the Ptolemaic system truly represents the relative movements of the sun and planets, and that the heliocentric scheme of Copernicus is a "prétendu système." If, indeed, M. Faye prefers to avail himself of the admission made above, to relegate Mr. Piddington's typical cyclones to the category of "prétendus cyclones," and therefore to exclude them from his theory, my present argument falls to the ground; but in that case his cyclone becomes the mere abstract definition of a term, and it remains to be shown that there is anything corresponding to it in Nature. That, however, in his latest communication to the *Comptes rendus*, he intended his assertions to apply to these tropical cyclones is abundantly apparent.

Can it be that M. Faye is unacquainted with the mass of original evidence embodied in the Indian cyclone reports, in Mr. Meldrum's writings on the cyclones of the South Indian Ocean, and with Prof. Loomis's work, in which these and many others are discussed? It would indeed seem so, since in none of his writings have I ever seen any reference to any other Indian author than Mr. Piddington, and even in his case it is difficult to believe that M. Faye has done more than simply accept Mr. Piddington's conclusions, without attempting to verify them by an examination of the original data. But if this be really the case—if he has taken so little pains to ascertain the fundamental facts, and to test the soundness of his speculations by an appeal to the evidence of the last twenty-five years—it is indeed strange that he can put forward confident assertions on a matter with which his acquaintance is so imperfect, and that he can disseminate statements that are demonstrably erroneous, and may be fraught with danger to the lives and property of those who accept him as their guide, backed with the high authority that must necessarily attach to his name.

It is a far from edifying spectacle to see such a man, in his latest communications to the *Comptes rendus*, quoting with complacency any isolated passage in the writings of leading meteorologists which seems to promise some support to his tottering theory, and ignoring all that would tell against it. That such cyclones as originate beyond the tropics are, in the first instance, movements of the higher atmosphere, has been rendered very probable by Dr. Hann's demonstration of the temperature relations of cyclones and anticyclones; but nothing that Dr. Hann has ever written has shown that he is in the least inclined to accept M. Faye's strange hypothesis of a descending current as the leading feature of cyclones and tornadoes. That the clearing of the skies in the central calm of a tropical cyclone may be due to the descent of a certain amount of air, although not decisively proved, is yet not improbable; but what would be thought of a man who, standing on a river bank, and seeing an upward current in the back-water immediately below him, should shut his eyes to the broad stream beyond, and assert, on the strength of his observation, that rivers flow from the sea to the mountains? Yet such, and no other, is the relation of this descending current to the great body of the cyclone. All may admit, with Prof. von Bezold, that there is much in the views hitherto prevalent as to the origin of cyclones and anticyclones that requires modification, and it may yet be long before these phenomena are fully and satisfactorily explained. There are many points of difference between the storms of the tropics and those of the temperate zone which seem to show that the forces that are principally active in the former play but a secondary part in the latter. But certainly there is no apparent tendency on the part of the leading meteorologists of Europe and America to accept M. Faye's *idolon specus* as a true theory of cyclones and tornadoes, nor is it in the least likely that such will ever be witnessed.

HENRY F. BLANFORD.

NOTES.

THE arrangements for the meeting of the British Association are now nearly complete. In a former note we referred among other matters to the excursions. We now learn that among them the organization of the pedestrian excursions to the Black Mountains is so far advanced that the detailed programme is now ready, and can be obtained by application to the Local Secretaries.

THE Royal Archæological Institute of Great Britain and Ireland opened their annual meeting in Edinburgh on Tuesday. At noon there was a reception of the members in the National Portrait Gallery by the President and Council of the Society of Antiquaries of Scotland. The inaugural meeting took place in the lecture-hall of the Royal Geographical Society. Sir Herbert Maxwell, on taking the chair, remarked that the closing years of a century naturally suggested the process of stock-taking, and as they had arrived at the last decade of a century which claimed to have witnessed beyond all precedent the accumulation of scientific knowledge, it was not unnatural that they should direct inquiry into the standing obtained by that particular branch of science in which they were all concerned. After a brief summary he stated that one of the problems which was pressing upon antiquaries at the present time was that relating to those mysterious rock sculptures which from time to time were found in increasing numbers all over Scotland. They bore a striking resemblance to similar rock sculptures found not only in Scandinavia and Central Europe, but in such remote parts of the earth as Asia, and Northern, Central, and Southern America. They could hazard no guess even at the race by whom they were made, still less at the object of their authors. All they could do was to record the discovery of them with careful drawings, and wait till perhaps light would flash upon them from the habit of some uncivilized tribe or from a passage in some hitherto unnoticed writer.

In the evening Dr. John Evans opened the Antiquarian Section with an address on the progress of archæology. The address covers the whole ground from Christy and Lartet's researches on the Dordogne to the Assyrian tablets.

BY an Imperial Decree of June 8, the Gold Medal for Art and Science was bestowed by H.I.M. the Emperor of Austria on Dr. R. Bowdler Sharpe, of the British Museum.

AT the graduation ceremony of the University of Edinburgh, held on the 1st inst., the Cameron prize was presented to Dr. Ferrier, F.R.S., by Prof. Fraser. Prof. Fraser said that Dr. Ferrier's researches had gained for him a well-merited fame throughout the whole civilized world. He had contributed to the alleviation of suffering in some of its most distressing and painful manifestations, and therefore the Senatus had thought that they were fully justified in awarding to him the prize, which had been founded for the recognition of important and valuable contributions to practical therapeutics. He had much pleasure in announcing further that Dr. Ferrier would, early next session, communicate to the University a paper describing some portion of his researches into this important subject. Prof. Ferrier, on appearing upon the platform to receive the prize, was received with most enthusiastic cheers.

AT a meeting of the Academy of Medicine of Paris on the 28th ultimo, Sir Joseph Fayrer, of London, and Dr. Bateman, of Norwich, were elected Associates of the Academy. These gentlemen had both been for some years Correspon ling Members of the Academy, but they shared the Membership with only six other members of the profession in this country, viz. Sir James Paget, Bart., Sir Richard Owen, Sir Joseph Hooker, Sir Thomas Longmore, Dr. West, and Sir Spencer Wells, Bart.

DR. THORNE THORNE, F.R.S., has been elected a Corresponding Member of the Royal Italian Society of Hygiene.

PROF. DU BOIS-REYMOND has been elected Dean of the Medical Faculty of the Berlin University for this year. He has already more than once filled this post. Prof. Foerster, the astronomer, has been chosen Rector of the University.

HER MAJESTY'S Commissioners for the Exhibition of 1851 have offered nomination to Science Scholarships for the year 1892 to the following Universities and Colleges. The Scholarships are of the value of £150 a year, and are tenable for two years. The scholars are to devote themselves exclusively to study and research in some branch of science the extension of which is important to the industries of the country:—University of Edinburgh, University of Glasgow, University of Aberdeen; Mason College of Science, Birmingham; University College, Bristol; Durham College of Science, Newcastle; Yorkshire College, Leeds; University College, Liverpool; Owens College, Manchester; University College, Nottingham; Firth College, Sheffield; University College of North Wales, Bangor; Queen's College, Cork; Queen's College, Galway; University of Toronto, University of Adelaide, University of New Zealand.

IT has been decided to perpetuate the memory of the connection of Dr. Leidy with the University of Pennsylvania by raising a fund to endow the Chair of Anatomy and to found a memorial museum. Dr. Leidy was Professor of Anatomy for thirty-nine years, and his devoted services will be suitably recognized by connecting his name with the chair which he so long adorned.

THE arrangements for the World's Fair at Chicago seem to be advancing quickly. Seeing that so much benefit to science may be anticipated from the comparison of the best instruments and methods of working in use in different countries, which such exhibitions render possible, it seems a pity that political questions may render them less representative than might be wished. The *New York Nation* refers to the reluctance of French manufacturers to take part in the World's Fair, due to the bad feeling created by the McKinley Bill, and to the belief entertained that any expense incurred in exhibiting goods would be lost by reason of the commercial restrictions which that measure was intended to create and has created. "Nobody cares to spend his money for mere purposes of show. Unless trade follows as a consequence of the exhibition, the money will be sunk. . . . . It does not advance matters, or help on the Fair, to show that both countries are wedded to a false system. It should serve, however, to open the eyes of people on both sides to the absurdity of inviting each other to show their goods, and then creating barriers to prevent each other from buying and selling. Imagine an American McKinleyite meeting his French brother at a World's Fair in Paris or in Chicago, and exhibiting to the latter a choice lot of provisions put up in Mr. Armour's most approved style, while the latter exhibits a fine assortment of woollens, silks, gloves, &c. If they could look in each other's faces without laughing, they must have a gravity exceeding that of two Roman augurs. Ordinary self-respect ought to teach the commercial classes of both countries to keep away from World's Fairs until they learn the A B C's of trade."

E pur si muove. Technical instruction in the provinces is growing apace, small thanks to our statesmen and legislators, for we owe to an accident the possibility of meeting the most crying needs of the time. We may refer to what is going on in Lancashire as an indication of the general awakenment. The total sum available for technical instruction is £40,391, and, after the sums already guaranteed by the County Council and some special amounts now in question are taken into account, there is a balance of about £29,000 to be dealt with, which the committee of the Council recommend should be apportioned between the urban and rural districts of the administrative county on the dual basis of rateable value and population. The committee recommend that a director of technical instruction be appointed at £500 per annum, with travelling expenses; that £3600 be set apart to provide twenty scholarships not exceeding £60 each for a term not exceeding three years, apportioned as follows—eight for science (tenable at Owens College, Liverpool University College, or other approved public institution), two for art, four for commercial subjects, and six for the science of agriculture, including horticulture; that £1200 be set apart for providing eighty exhibitions of £15, tenable for one year at Owens College and Liverpool University College evening classes, or at some approved technical, commercial, or intermediate school, to be apportioned as follows—thirty-two exhibitions for science, eight for art, sixteen for commercial subjects, and twenty-four for agriculture; that £2000 be set apart for founding travelling scholarships and free studentships of £1 to £10 to assist students in attending technical schools; that the various urban and rural sanitary authorities, through or in conjunction with any district committees that may be appointed, be permitted to nominate candidates for the above, two-thirds of whom shall be children of parents whose incomes do not exceed £300 per annum; that all the scholarships and exhibitions be opened to students of both sexes resident in the county; that a sum not exceeding £1000 be granted for the purpose of aiding University Extension lectures; that a sum not exceeding £500 be granted to carry out the arrangements with the council of the Harris Institute in Preston for the promotion of technical instruction in agriculture; and that a sum not exceeding £1000 be granted for staff and office expenses. The migratory dairy school having been much appreciated, arrangements have been made to start a second school at Ulverston on August 11. A scheme for agricultural

Digitized by Google

instruction is also being arranged (estimated to cost £500 per annum), but the details have not yet been finally settled.

THE managers of the New Gallery announce a "Victorian Exhibition," covering the fifty years of Her Majesty's reign from 1837 to 1887. As in the case of the preceding exhibitions, it will contain pictures and other records of events illustrating the history of the Royal Family and of the nation; and it will contain, above all, a series of portraits of the illustrious men and women who, in so many different ways, have made their mark upon the age. We gather from an article in the *Times* that science, in this of all reigns, is not likely to fall behind. We are promised pictures of Charles Darwin, Faraday, and Sir John Herschel, of Lyell and Murchison, of the two Stephensons, of Fox Talbot, one of the inventors of photography, and of Wheatstone, one of the inventors of the telegraph. The article adds that "it would be easy to quadruple this list, supposing the eminent men of science to have had the time and the vanity to sit for their portraits." We agree.

THE *Pall Mall* returns to the charge on the subject of the imagined unpopularity of the British Museum, and states that although the evening openings have so far been a failure, and a very costly failure, the first installation of the electric light costing over £17,000, the problem is being carefully considered. It is also stated that it is an open secret that for some years past the Trustees have been unanimous in favour of Sunday opening, which, as they have more than once pointed out, would entail little or no extra work on the officials, but merely change of work for a few policemen. Among the things that are wanted are certainly continuity in the hours during which the Museum is open on any one day, and the possibility of obtaining some decent refreshment. If in these matters the Trustees will imitate he arrangements at the South Kensington Museum, we believe the attendance will be increased—the attendance of workers certainly will.

WE are requested to state that the designs submitted in competition for the completion of the buildings of the South Kensington Museum are now on view at that Museum from 10 till 6.

DURING the whole month of July little variation in the state of Vesuvius was observable; the lava flowed steadily on, and had at one time extended down the Fossa della Vetrana, nearly opposite the lodge and gate of Messrs. Cook's private road to the Vesuvian railway, but immediately cooled, and again started flowing much nearer its source. At the summit of Vesuvius the vapour appeared to issue almost as in the normal state of the mountain, except for momentary interruptions and occasional ejection of dust and sand. Dr. Johnston-Lavis, who has recently visited the scene, sends us the following details:—"On July 30, I again visited the top of the great cone. The central crater has considerably enlarged, and has now an elliptical plan, with the major axis directed north-west to south-east, but this form has been derived from its original circular shape by the greater destruction of the lips towards the south-east. The edges were in a most unstable state, and attempts at photographing the interior were accompanied by considerable danger, and required many precautions. On the inner walls I was, however, able to make out several dykes besides the hollow one that has supplied the great eastern rift for its several eruptions from 1881–82 to 1890. These may be enumerated as directed north-east; north-north-west, probably the dyke formed at the commencement of this eruption; north-west; south-west, probably the cooled upper extremity of the lava sheet filling the south-west fissure which I have so often mentioned; and lastly, the hollow dyke to the south-south-east, which supplied the lava of May 1885, is again exposed. There may be other dykes, but the large amount of vapour filling the crater, and the danger and impossibility of approaching the edges in most parts, prevent a very detailed examination. So far as I could make out, the situation of the vent is quite to the south-east of the crater bottom, so that this fact, combined with the prolongation of the crater in that direction and the existence of numerous radial fissures, would indicate that the general tendency is for the next lateral disruption to take place towards Pompeii, or Torre Anunziata. On July 30 the lava was flowing very slowly just at the junction of the Atrio del Cavallo and the Fossa Vetrana. To an experienced observer the whole state of the mountain is still very unstable, and a fresh outburst might occur at any moment, although the volcano may gradually quiet down. But a few days before my visit, four strong earthquakes were felt at the lower railway station, showing that important fracturing, injection, or other dynamic disturbances were taking place in the great cone."

WE have received from Mr. C. Mostyn an interesting letter on the well-known appearance of the green ray at sunrise or sunset caused by the refraction of the air. He states:—"This 'green ray' is seen to best advantage at sun-*rise*, owing I imagine to the eye not being wearied with watching the previous glare, as is apt to be the case at sunset. At the same time, I had many very satisfactory observations at sunset, one in particular, when we were running before a very heavy sea in the Southern Ocean, and the 'green ray' was seen no less than three times in as many seconds, as the ship rose and fell on the huge waves causing as it were two sunsets, with a sunrise between them. The best displays took place when the refraction near the horizon was of such a character that the sun assumed a balloon, or vase, shape as he came close to the sea-line. When, on the contrary, the sun appeared flattened out in its horizontal diameter, the 'green ray' was either entirely absent, or was seen only in an indistinct and uncertain manner."

SIR EDWARD WATKIN having now, we presume, cured unpunctuality on the many lines of railway which he is highly paid to manage, is again turning his attention to Snowdon. It will be remembered that he proposed in the first instance to erect an astronomical observatory there. This, of course, was ridiculous. We are now told that the authorities of the Trinity House have expressed warm approval of his more recent proposal to place an electric light on the summit. The Elder Brethren consider that the light should prove an invaluable addition to those already erected round the North Wales coast for the guidance of mariners. Sir Edward hopes to have the light burning before Christmas.

THE Directors of the Crystal Palace, in deference to the wish of the Electrical Trade Section of the London Chamber of Commerce, have decided to postpone the opening of the Electrical Exhibition from November 1891 till January 1, 1892, on which date the Exhibition will be formally opened.

WE learn from the *Photographic News* that the great progress that has been made in the methods by which rapid movements can be analyzed is well seen in a series of photographs lately taken by Anschütz, of Lissa, who has already given to the world some of the best instantaneous pictures ever taken. The subject of the pictures at present under consideration is a dog jumping over a small bush. In the act of making one jump the animal has been photographed twenty-four separate times, and each picture is not a mere silhouette, as was the case with Muybridge's first attempts of this kind, but a little picture showing half-tone and detail. Some of the attitudes are, of course, comic in appearance, for they represent phases of a movement which the eye is unaccustomed to, and cannot possibly appreciate. Notably is this the case in the commencement of the jump, when the dog's hind toes only touch the ground; and again at the finish of the jump, when his legs are gathered together in a heap.

A GERMAN specialist, Dr. Cold, has recently pleaded for giving young people more sleep. A healthy infant sleeps most of the time during the first weeks; and, in the early years, people are disposed to let children sleep as much as they will. But from six or seven, when school begins, there is a complete change. At the age of ten or eleven, the child sleeps only eight or nine hours, when he needs at least ten or eleven, and as he grows older the time of rest is shortened. Dr. Cold believes that, up to twenty, a youth needs nine hours' sleep, and an adult should have eight or nine. With insufficient sleep, the nervous system, and brain especially, not resting enough, and ceasing to work normally, we find exhaustion, excitability, and intellectual disorders gradually taking the place of love of work, general well-being, and the spirit of initiative.

THE *Entomologist's Monthly Magazine*, among much interesting matter, refers to the possibility of the destruction of some of the inclosures in the New Forest which have proved themselves to be among the happiest hunting-grounds of the entomologist.

A RECENT number of the Proceedings of the Academy of Natural Sciences of Philadelphia contains a paper on Echinoderms and Arthropods from Japan, by Mr. J. E. Ives. The specimens described were collected by Mr. Frederick Stearns, of Detroit. The new species of Echinoderms and Crustacea are enumerated. A new Ophurian, a new crab, and a new Pycnogonoid are described, and several species of star-fishes hitherto unfigured are illustrated. The plates are admirable.

BULLETIN No. 10 of the University College of Agriculture at Tokyo contains an account of some manuring experiments with paddy rice (second year) by Dr. O. Kellner, Y. Kozai, Y. Mori, and M. Nagaoka. The principal purpose of the researches carried out in 1889, and reported in Bulletin No. 8, was to ascertain how much nitrogen, phosphoric acid, and potash can be consumed by rice from the stock of nutrients in the unmanured soil, and how much of them is needed in the manure for the production of a maximum crop if the three nutrients are applied in the most assimilable form. On the basis of the results then obtained, the present experiments were tried with the object of getting information on the following questions:—(1) How much nitrogen, phosphoric acid, and potash is taken up from those plots which had not received the respective nutrients in the preceding year? (2) What is the effect of unrecovered phosphatic manure on the succeeding crop? (3) How much nitrogen can be supplied to rice by the preceding cultivation of a leguminous plant (*Astragalus lotoides*, Lam.) for green manuring? (4) What is the effect of various phosphatic fertilizers on rice? (5) What is the effect of various nitrogenous manures on rice? The work seems to have been carefully done, and affords a good instance of the way in which scientific questions are now being treated in Japan.

THE July number of the Proceedings of the Society for Psychical Research has reached us, and contains the following contributions:—"On Alleged Movements of Objects, without Contact, occurring not in the Presence of a Paid Medium," by Mr. F. W. H. Myers; "Experiments in Clairvoyance," by Dr. A. Backman; and "A Case of Double Consciousness," by Mr. R. Hodgson.

AT the Bournemouth meeting of the British Medical Association, a discussion on the subject of alcohol was initiated by a paper by Dr. Samuel Wilks. In the course of his paper he stated that he had no acquaintance with any organic changes attributable to alcohol in the lungs and kidneys, but it seemed that the digestive and nervous systems suffered. Physiologists had failed to demonstrate the chemical changes which it underwent in the body, and consequently it was impossible to say whether it was of the nature of a food or not. No one had yet seen a person who lived on alcohol, although there was evidence of persons taking large quantities of alcohol who yet preserved their weight with a minimum of food; and that supported the theory that, although alcohol was not nutritive in itself, it prevented the wear and tear of the body. The opposite theory also existed, that alcohol acted as a spur to the nervous system and quickly wore it out. He could not disapprove of the use of wine and beer, if taken in moderation, by the masses of the people; but as to spirits or spirits and water, he had not made up his mind that they were in any way useful, and he seldom recommended them. Dr. Bucknill thought that the wise use of wine might cure some cases and be useful in others. Dr. Norman Kerr said that alcohol was a poison, analogous in many respects to other poisons. Sir Risdon Bennett agreed with Dr. Wilk in not approving of spirits as a beverage. He believed it to be useful in fever and in some nervous diseases, but he did not think it desirable at the present time to lay down any broad principles with regard to alcohol with reference to the whole community.

THE Philadelphia *Satellite* states that, during the abortive attempt to cut a canal through the isthmus of Panama, as much as 200,000 ounces of quinine were used annually in combating malarial fever.

ACCORDING to the *Pharmaceutical Journal of Australia*, the practice has been introduced into Victoria, on the recommendation of Baron von Mueller, of placing green branches of eucalyptus in sick rooms as a disinfectant. Dr. Curgenven states, after twelve months' trial, that in cases of scarlet fever, if the branches be placed under the bed, the bedding undergoes thorough disinfection, the volatile vapour penetrating and saturating the mattress and every other article in the room. Its vapour is also said to have a beneficial effect upon phthisical patients, acting not only as an antiseptic, but as a sedative and to some extent as a hypnotic.

THE Bulletin of the (American) Essex Institute just received contains an account of the annual meeting held last May, and a retrospect of the year, from which we learn that Mr. Perley, in a lecture on "Old-time Winters in Essex County," gave interesting particulars on many subjects, including weather. We give the following extract:—"The lecturer spoke of the watch, church services, dress, food, and schools of the early winter seasons; how the people spent their evenings, the winter employment of the people in cutting off the forests, sledding timber and wood, making pipe staves and barrel hoops, and, most interesting of all, the institution of the old-fashioned shoemakers' shops, of which nearly every farm had one a century ago. Women in those days engaged in spinning and weaving. The holidays were referred to—Thanksgiving, Christmas, and New Year's; and the winter pleasures, such as sleigh-rides, dancing, spinning and quilting parties, and games, shuffle-board, coasting, skating, trapping, gunning, fishing, singing-schools, and girls' samplers. He also spoke of the old modes of travel, snow-shoes, &c. Nearly all the heavy teaming was done on sleds, and he mentioned the winter of 1768-69, when the travelling was so bad that the farmers in the western part of the State could not get their grain and provisions to the coast to market. Snow remained on the roads as it fell until about a century ago. Mr. Perley then spoke of particular winters: that of 1641-42, when the Indians said they had not seen the ocean so much frozen for forty years; of 1646-47, when there was no snow to lay; of 1696-97, said to be the coldest winter since the first settlement of New England; of 1701-2, which was 'turned into summer'; of 1717-18, when the snow was from ten to fifteen feet deep and the drifts twenty-five feet, many one-story houses being buried; of 1740-41, said

Digitized by Google

to be the severest winter known by the settlers, Salem Harbour being frozen over as early as October; of 1774-75, a wonderfully mild winter; of 1779-80, when for forty days, including March, there was no perceptible thaw, and the snow was so hard and deep that loaded teams passed over the fences in any direction, arches being dug under the snow so that men on horseback could ride under them, and which was long remembered as *the* hard winter; of 1784-85, when, as late as April 15, snow was 2 feet deep, and frozen hard enough to bear cattle; of 1785-86, when in the remarkable storm of November 25, the snow blew into balls, one of which had rolled 76 feet, measuring 17½ by 22 inches; of 1794-95, when the *Betsey* was launched in Salem on Christmas Day, the thermometer indicating 85° above zero at noon, and men and boys went in swimming; of 1801-2, when the *Ulysses*, *Brutus*, and *Volutia*, three Salem vessels, which sailed out of the harbour on a summer-like morning in February, were all cast away at night on Cape Cod, in a terrible snow-storm, which continued a week. He also referred to more recent seasons, and of the cold winter of 1856-57, when in one week in January was the coldest day by the thermometer ever recorded of late years, mercury in Salem 20° below zero; travel on the railroad between Boston and Salem entirely suspended from Tuesday morning to Thursday afternoon. The recent mild winters were also alluded to."

IN the volume of Bavarian meteorological observations for 1890, Dr. C. Lang (the Director of the Service) contributes an article on the "Secular Variations of Damage by Lightning and Hail." He points out that in almost all recent investigations the conclusions come to are that during the last 50 years damage by lightning has much increased, but this is not borne out by his inquiry, but is probably owing to more attention having been paid to the subject recently. The numerous impurities introduced into the air of towns from fire-places, &c., would make it probable that they would be more liable to damage than country places, but exactly the opposite is the case, the ratio of damage to buildings in towns to that in the country being 1 : 2. This result is possibly to some extent due to the more numerous lightning-conductors, and to railway lines in the towns. He finds that the damage from hail shows a very probable connection with the period of sun-spot frequency, but the secular range of the former points more particularly to the influence of temperature, so that the curve of hail-frequency shows, not only a minimum occurring with the 11-year sun-spot maximum, but also a period of about 35 years. The damage from lightning, on the other hand, does not show any connection with a secular range of temperature, but the minimum occurs with the maximum of sun-spot frequency. In other words, damage from hail seems to be more decidedly connected with terrestrial, and damage from lightning more with cosmical influence.

THE application of science in the direction of domestic comfort seems to be advancing with great strides in the United States. The *Nation*, in reference to the announcements that the inhabitants of Kansas City are about to be supplied with cool air in summer and warm air in winter through a system of pipes laid in the streets; and that the people of Framingham, Mass., are to be furnished with gas for heating purposes at the price of 50 cents a thousand feet, thus writes:—"Thus the ends of the land are advancing in the art of living while the metropolis remains tationary, and is kept from falling behind only by incessant grumbling. And yet the possibilities of comfort, of health, and ven of cheapness revealed in these schemes are wonderfully alluring, and their realization would be prevented by no physical obstacles. If we consider that wonderful work of human hands, the kitchen range, under the management of the regular cook, who knows how to put on all the draught at once and keep it on, what a devourer of fuel it is! We need a cup of tea or a chop in summer, and a fire is kindled that would generate steam enough to drive an ocean racer a mile upon her course, the kitchen is turned into a Tophet, the miserable servants swelter in the apartments which their own stupidity and that of mankind have rendered uninhabitable, and their employers are rendered uncomfortable above. The extravagance of the Chinese, who, as related by Charles Lamb, at first thought it necessary to burn down a house whenever they wanted to roast a pig, is nothing to ours." Has anybody ever calculated the annual waste caused by the above described "use" of the ordinary "kitchen range"?

AN interesting paper upon the slow combustion of explosive gas mixtures is contributed to the current number of *Liebig's Annalen* by Dr. Krause and Prof. Victor Meyer. The experiments described were made with electrolytic mixtures of hydrogen and oxygen, and detonating mixtures of carbon monoxide and oxygen. The first experiment consisted in heating in a bath of vapour of diphenylamine (305°) a detonating mixture of hydrogen and oxygen contained in a U-shaped tube closed by mercury. The heating was continued without intermission for a fortnight, at the end of which time very little gas remained, almost the whole having slowly combined to form water. The experiment was then repeated in an apparatus constructed entirely of glass, and in which the use of mercury was avoided, except in a small manometer used to indicate the pressure. It was then found that no trace of water was formed at the temperature of diphenylamine vapour (305° C.); at the temperature of boiling sulphur (448°) the amount of combination was exceedingly small; while at 518°, the boiling-point of phosphorus pentasulphide, a considerable amount of combination occurred, but no quantitative rule could be deduced. In all these experiments the gases employed were moist, and no particular care had been taken to remove the last traces of admixed air. Now Bunsen and Roscoe, in their celebrated work on detonating mixtures of hydrogen and chlorine, showed that regular results were only obtained when the film of air condensed upon the surfaces of the glass vessels employed was removed by allowing the gas to stream through the apparatus for several days previous to the experiment. A fresh series of experiments were therefore made, in which these precautions were most rigidly observed; most complicated pieces of apparatus were constructed of glass throughout, which admitted of the drying of the gases prepared (in case of hydrogen and oxygen) by the electrolysis of hot water, so as to exclude ozone and hydrogen peroxide; and the pure gases thus obtained were allowed to stream through the series of bulbs united by capillary tubes for a fortnight, night and day, before the bulbs were sealed off at the capillaries. It was found that, with pure dry gases, scarcely a trace of combination occurred by the fusion of the very fine capillaries. As regards the temperature of ignition of electrolytic hydrogen and oxygen, or detonating carbon monoxide and oxygen, it was found that bulbs containing them do not explode when placed in boiling pentasulphide of phosphorus (518°), but do explode in vapour of stannous chloride (606°). The temperature of ignition lies, therefore, between 518° and 606° C. The mode of explosion differs considerably under different circumstances. In case of explosion in vapour of stannous chloride, the bulb was never shattered, but a sudden appearance of flame within the bulb occurred, accompanied by a slight detonation, and in some cases the point of the capillary was blown off. It is also astonishing how long one requires to hold such a bulb in a Bunsen flame before explosion occurs; it never occurs until the flame becomes coloured yellow, and the glass begins to soften, and frequently only causes a swelling out of the glass at the heated spot. Thin-walled bulbs, however, are sometimes shattered. In two cases it was noticed that the glass at the softened part was violently

Digitized by Google

forced in, owing to the previous heating having caused a large percentage of combination, and hence the production of a partial vacuum. Even after taking the rigid precautions to insure purity above described, no definite quantitative rule connecting the time and percentage of combination has been discovered, experiments performed simultaneously upon similarly treated mixtures yielding widely different results; showing that the irregularities of glass surfaces, even after removal of their air-films, are quite sufficient to modify very sensibly the conditions under which combination occurs.

THE additions to the Zoological Society's Gardens during the past week include an Egyptian Gazelle (*Gazella dorcas*) from North Africa, presented by Mr. S. C. Saunders; a Ring-tailed Coati (*Nasua rufa*) from South America, presented by Mr. Edward J. Brown; two Herring Gulls (*Larus argentatus*), British, presented by Mr. T. A. Cotton; two White-bellied Sea Eagles (*Haliaëtus leucogaster*) from Australia, presented by Mr. Hugh Nevill, F.Z.S.; a Lesser Sulphur-crested Cockatoo (*Cacatua sulphurea*) from Moluccas, presented by Miss Partridge; three Barbary Turtle Doves (*Turtur risorius*) from North Africa, presented by Miss D. Bason; an Indian Cobra (*Naia tripudians*) from India, presented by Mr. H. E. Lindsay; two Harnessed Antelopes (*Tragelaphus scriptus* ♂ ♀) from Gambia, a —— Paradoxure (*Paradoxurus aureus*) from Ceylon, two Grey Ichneumon (*Herpestes griseus*) from India, four grey Parrots (*Psittacus erithacus*) from West Africa, deposited.

OUR ASTRONOMICAL COLUMN.

THE SPECTRUM OF β LYRÆ.—A study of twenty-nine photographs of the spectrum of β Lyræ has led to some interesting results, noted by Prof. E. C. Pickering in *Astronomische Nachrichten*, No. 3051. The spectrum of this star contains, in addition to the absorption lines, several bright lines, the most conspicuous of which are about λλ 486, 443, 434, 410, 403, and 389, to use a three-figure reference. The lines near λ 443 and λ 403, are two of the most prominent lines in the spectra of the Orion stars, and the remaining four coincide with the hydrogen lines F, G, *h*, and α. From the investigation it appears that these bright lines change their positions, so that sometimes they have a greater wave-length than the corresponding dark lines, whilst at other times the reverse is the case. In some of the photographs several bright lines are double, and the dark lines are also not free from changes. This naturally led to the inquiry as to whether the changes were connected with the variations of the star's brightness. Starting from a minimum of brightness there is a maximum at 3d. 5h., a secondary minimum at 6d. 11h., another maximum at 9d. 16h., and then the principal minimum is again reached after a total period of 12d. 22h. The point of interest is that the fourteen plates in which the wave-length of the bright lines was increased were taken during the first half of this period of variation—that is, before the secondary minimum; whilst on the eleven plates taken during the second half of the period the displacement was towards the blue end of the spectrum. And since the photographs extend over more than four years, there can be little doubt that the displacements are intimately connected with the variations of the star's brightness. One of the explanations suggested by Prof. Pickering to account for the observed phenomena is that the bright lines are emitted by an object revolving in a circular orbit round the principal star, with a maximum velocity of about 300 miles per second, and completing its circuit in a period of 12d. 22h. The corresponding periastron distance is about 50,000,000 miles. If this be so, β Lyræ is a binary of the β Aurigæ type, but differing from it in the fact that the component stars have unlike spectra. The phenomena could also be produced by a meteor stream, or by an object like the sun, rotating in 12d. 22h., and having a large protuberance on it extending over more than 180° of longitude. The study of the additional photographs which are being taken will doubtless elucidate the matter.

THE POLARIZATION THEORY OF THE SOLAR CORONA.—In the Publications of the Astronomical Society of the Pacific, vol. iii. No. 16, 1891, Prof. Frank H. Bigelow gives some further results of his investigations of coronal forms, and arrives at some new results. It can be shown that in the case of repulsion of matter in a spherical rotating body like the sun, two poles of repulsion are formed, and the body is polarized about an axis. Within the body the lines of force are parallel to the axis of polarization, and their curvature outside the surface may be calculated. Applying these considerations to the similar coronal forms exhibited in the eclipse photographs of July 1878 and January and December 1889, Prof. Bigelow finds that the axis of polarization is at the surface of the sun about 4½° from the axis of rotation, and taking the radius of the sun as 866,500 miles, the length of the axis to which the lines of force are parallel is 1,729,700 miles. Its direction is fixed, and in 1878 the north and south coronal poles had the positions, north pole = 201°·2, south pole = 301°·6, when referred to the ascending-node of the sun's equator on the plane of the ecliptic. If 138 + 349°·85, 151 + 311°·40, and 12 + 312°·55 be taken as the number of revolutions and the angular excess during the three intervals between the dates of the above eclipses, the mean daily motion in longitude at the latitude of the coronal pole, 85°·5, is found to be 13°·13307. From this the following periods of the sun's rotation in latitude 85°·5 is deduced—

Sidereal period 27·41171d. = 27d. 9h. 52m. 52s.
Synodic period 29·63580d. = 29d. 15h. 15m. 33s.

The formula proposed to express the rotation-period in different solar latitudes is $X = 862' - 76' \sin l$, where X is the mean daily motion in minutes, and *l* the latitude. With these elements it is possible to predict the positions of the coronal poles at any epoch, and in consequence the relative form of the corona at the time, as seen from the earth. A comparison of the calculated results and photographs, obtained during some recent eclipses, displays a striking concordance. The investigation "also serves to strengthen the conviction that the sun-spots are probably formed by the descent of material from the extremities of the coronal streamers, in a vertical direction upon the sun."

OBSERVATIONS OF THE MOTION OF SIRIUS.—At the Berlin Academy of Sciences on June 4, Prof. Vogel communicated some observations of the motion of Sirius in the line of sight. Using the iron spectrum as the term of comparison with the spectrum of the star, it was found that the velocity of approach on March 22 was 1·96 geographical miles per second with respect to the sun. With hydrogen comparison lines the velocity found was 1·73 miles per second.

RETURN OF ENCKE'S COMET.—A telegram from the Lick Observatory to Prof. Krüger, announces that Encke's periodic comet has been observed on its return by Mr. Barnard on August 1·9958 G.M.T., in the position R.A. 3h. 55m. 20·6s., Decl. 29° 59′·1 N.

ON SOME TEST CASES FOR THE MAXWELL-BOLTZMANN DOCTRINE REGARDING DISTRIBUTION OF ENERGY.[1]

(1) MAXWELL, in his article (*Phil. Mag.*, 1860) "On the Collision of Elastic Spheres," enunciates a very remarkable theorem, of primary importance in the kinetic theory of gases, to the effect that, in an assemblage of large numbers of mutually-colliding spheres of two or of several different magnitudes, the mean kinetic energy is the same for equal numbers of the spheres irrespectively of their masses and diameters; or, in other words, the time-averages of the squares of the velocities of individual spheres are inversely as their masses. The mathematical investigation given as a proof of this theorem in that first article on the subject is quite unsatisfactory; but the mere enunciation of it, even if without proof, was a very valuable contribution to science. In a subsequent paper ("Dynamical Theory of Gases," Phil. Trans. for May 1866) Maxwell finds in his equation (34) ("Collected Works," p. 47), as a result of a thorough mathematical investigation, the same theorem extended to include collisions between Boscovich points with mutual forces according to any law of distance, provided only that not more than two points are in collision (that is to say, within the distances of their mutual influence) simultaneously. Tait confirms Maxwell's original theorem for colliding spheres of different

[1] Paper read at the Royal Society by Sir William Thomson, D.C.L., P.R.S., on June 11, 1891.

Digitized by Google

magnitudes in an interesting and important examination of the subject in §§ 19, 20, 21 of his paper "On the Foundations of the Kinetic Theory of Gases" (Trans. R.S.E. for May 1866).

(2) Boltzmann, in his "Studien über das Gleichgewicht der lebendigen Kraft zwischen bewegten materiellen Punkten" (*Sitzb. K. Akad. Wien*, October 8, 1868), enunciated a large extension of this theorem, and Maxwell a still wider generalization in his paper "On Boltzmann's Theorem on the Average Distribution of Energy in a System of Material Points" (Cambridge Phil. Soc. Trans., May 6, 1878, republished in vol. ii. of Maxwell's "Scientific Papers," pp. 713-41), to the following effect (p. 716):—

"In the ultimate state of the system, the average kinetic energy of two given portions of the system must be in the ratio of the number of degrees of freedom of those portions."

Much disbelief and doubt has been felt as to the complete truth, or the extent of cases for which there is truth, of this proposition.

(3) For a test case, differing as little as possible from Maxwell's original case of solid elastic spheres, consider a hollow spherical shell and a solid sphere—globule we shall call it for brevity—within the shell. I must first digress to remark that what has hitherto by Maxwell and Clausius and others before and after them been called for brevity an "elastic sphere," is not an elastic solid, capable of rotation and of elastic deformation; and therefore capable of an infinite number of modes of steady vibration, into which, of finer and finer degrees of nodal subdivision and shorter and shorter periods, all translational energy would, if the Boltzmann-Maxwell generalized proposition were true, be ultimately transformed by collisions. The "smooth elastic spheres" are really Boscovich point-atoms, with their translational inertia, and with, for law of force, zero force at every distance between two points exceeding the sum of the radii of the two balls, and infinite repulsion at exactly this distance. We may use Boscovich similarly for the hollow shell with globule in its interior, and so do away with all question as to vibrations due to elasticity of material, whether of the shell or of the globule. Let us simply suppose the mutual action between the shell and the globule to be nothing except at an instant of collision, and then to be such that their relative component velocity along the radius through the point of contact is reversed by the collision, while the motion of their centre of inertia remains unchanged.

(4) For brevity, we shall call the shell and interior globule of § 3, a double molecule, or sometimes, for more brevity, a doublet. The "smooth elastic sphere" of § 3 will be called simply an atom, or a single atom; and the radius or diameter or surface of the atom will mean the radius or diameter or surface of the corresponding sphere. (This explanation is necessary to avoid an ambiguity which might occur with reference to the common expression "sphere of action" of a Boscovich atom.)

(5) Consider now a vast number of atoms and doublets, inclosed in a perfectly rigid fixed surface, having the property of reversing the normal component velocity of approach of any atom or shell or doublet at the instant of contact of surfaces, while leaving unchanged the absolute velocity of the centre of inertia of the two. Let any velocity or velocities in any direction or directions be given to any one or more of the atoms or of the shells or globules constituting the doublets. According to the Boltzmann-Maxwell doctrine, the motion will become distributed through the system, so that ultimately the time-average kinetic energy of each atom, each shell, and each globule shall be equal; and therefore that of each doublet double that of each atom. This is certainly a very marvellous conclusion; but I see no reason to doubt it on that account. After all, it is not obviously more marvellous than the seemingly well-proved conclusion that in a mixed assemblage of colliding single atoms, some of which have a million million times the mass of others, the smaller masses will ultimately average a million times the velocity of the larger. But it is not included in Maxwell's proof for single atoms of different masses [(34) of his "Dynamical Theory of Gases" referred to above]; and the condition that the globules inclosed in the shells are prevented by the shells from collisions with one another violates Tait's condition [(C) of § 18 of "Foundations of K.T. Gases"], "that there is perfectly free access for collision between each pair of particles whether of the same or of different systems." An independent investigation of such a simple and definite case as that of the atoms and doublets defined in §§ 3-5 is desirable as a test, or would be interesting as an illustration were test not needed, for the exceedingly wide generalization set forth in the Boltzmann-Maxwell doctrine.

(6) Next, instead of only a single globule within the shell of § 4, let there be a vast number. To fix ideas let the mass of the shell be equal to a hundred times the sum of the masses of the globules, and let the number of the globules be a hundred million million. Let two such shells be connected by a push-and-pull massless spring. Let all be given at rest, with the spring stretched to any extent; and then left free. According to the Boltzmann-Maxwell doctrine, the motion produced initially by the spring will become distributed through the system, so that ultimately the sum of the kinetic energies of the globules within each shell will be a hundred million million times the average kinetic energy of the shell. The average velocity[1] of the shell will ultimately be a hundred-millionth of the average velocity of the globules. A corresponding proposition in the kinetic theory of gases is that, if two rigid shells, each weighing 1 gram, and containing a centigram of monatomic gas, be attached to the two prongs of a massless perfectly elastic tuning-fork, and set to vibrate, the gas will become heated in virtue of its viscous resistance to the vibration excited in it by the vibration of the shell, until nearly all the initial energy of the tuning-fork is thus spent.

(7) Going back to the double molecules of § 5, suppose the internal globule to be so connected by massless springs with the shell that the globule is urged towards the centre of the shell with a force simply proportional to the distance between the centres of the two. This arrangement, which I gave in my Baltimore Lectures, in 1884, as an illustration for vibratory molecules embedded in ether, would be equivalent to two masses connected by a massless spring, if we had only motions in one line to consider; but it has the advantage of being perfectly isotropic, and giving for all motions parallel to any fixed line exactly the same result as if there were no motion perpendicular to it. When a pair of masses connected by a spring strikes a fixed obstacle or a movable body, with the line of their centres not exactly perpendicular to the tangent plane of contact, it is caused to rotate. No such complication affects our isotropic doublet. An assemblage of such doublets being given moving about within a rigid inclosing surface, will the ultimate statistics be, for each doublet,[2] equal average kinetic energies of motion of centre of inertia, and of relative motion of the two constituents?

(8) If we try to answer this question synthetically, we find a complex and troublesome problem in the details of all but the very simplest case of collision which can occur, which is direct collision between two not previously vibrating doublets, or any collision of one not previously vibrating doublet against a fixed plane. In this case, if the masses of globule and shell are equal, a complete collision consists of two impacts at an interval of time equal to half the period of free vibration of the doublet, and after the second impact there is separation without vibration, just as if we had had single spheres instead of the doublets.

[1] The "average velocity of a particle," irrespectively of direction, is (in the kinetic theory of gases) a convenient expression for the square root of the time-average of the square of its velocity.

[2] This implies equal average kinetic energies of the two constituents; and, conversely, equal average kinetic energies of the two constituents, except in the case of their masses being equal, implies the equality stated in the text. Let u, u' be absolute component velocities of two masses, m, m', perpendicular to a fixed plane; U the corresponding component velocity of their centre of inertia; and v that of their mutual relative motion. We have

$$u = U - \frac{m'v}{m+m'}, \qquad u' = U + \frac{mv}{m+m'}; \quad \ldots\ldots (1)$$

whence

$$mu^2 + m'u'^2 = (m+m')\left[U^2 + \frac{mm'v^2}{(m+m')^2}\right] + \frac{4mm'}{m+m'}Uv. \quad \ldots (2)$$

Now suppose the time-average of Uv to be zero. In every case in which this is so, we have, by (2),

$$\text{Time-av.}\{mu^2 + m'u'^2\} = (m+m') \times \text{Time-av.}\left\{U^2 + \frac{mm'v^2}{(m+m')^2}\right\}. \quad (3)$$

Hence in any case in which

$$\text{Time-av. } mu^2 = \text{Time-av. } m'u'^2 \quad \ldots\ldots\ldots (4)$$

we have

$$(m+m') \times \text{Time-av.}\left\{U^2 + \frac{mm'v^2}{(m+m')^2}\right\} = \text{o}, \quad \ldots\ldots (5)$$

and therefore, except when $m = m'$, we must have

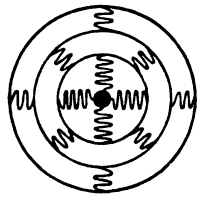
$$\text{Time-av. } (m+m')U^2 = \text{Time-av.} \frac{mm'v^2}{m+m'} \quad \ldots\ldots (6)$$

which proves the proposition, because, as we readily see from (1), $\frac{1}{2}mm'v^2/(m+m')$ is, in every case, the kinetic energy of the relative motions, $u - U$, and $U - u'$.

Digitized by Google

But in oblique collision between two not previously vibrating doublets, even if the masses of shell and globule are equal, we have a somewhat troublesome problem to find the interval between the two impacts, *when there are two*, and to find the final resulting vibration. When the component relative motion parallel to the tangent plane of the first impact exceeds a certain value depending on the radius of the outer surface of the shell, the period of free vibration of the doublets, and the relative velocity of approach; there is no second impact, and the doublets separate with no relative velocity perpendicular to the tangent plane, but each with the energy of that component of its previous motion converted into vibrational energy. When the mass of the shell is much smaller than the mass of the interior globule, almost every collision will consist of a large number of impacts. It seems exceedingly difficult to find how to calculate true statistics of these chattering collisions, and arrive at sound conclusions as to the ultimate distribution of energy in any of the very simplest cases other than Maxwell's original case of 1860; but, if the Boltzmann-Maxwell generalized doctrine is true, we ought to be able to see its truth as essential, with special clearness in the simplest cases, even without going through the full problem presented by the details. I can find nothing in Maxwell's latest article on the subject (Camb. Phil. Trans., May 6, 1878), or in any of his previous papers, proving an affirmative answer to the question of § 7.

(9) Going back to § 6, let the globules be initially distributed as nearly as may be homogeneously through the hollow; let each globule be connected with neighbours by massless springs; and let all the globules which are near the inner surface of the shell be connected with it also by massless springs. Or let any number of smaller shells be inclosed within our outer shell, and connected by massless springs, as represented by the accompanying diagram, taken from a reprint of my Baltimore Lectures now in progress. Let two such outer shells,



given at rest with their systems of globules in equilibrium within them, be connected by massless springs, and be started in motion, as were the shells of § 6. There will not now be the great loss of energy from the vibration of the shells which there was in § 6. On the contrary, the ultimate average kinetic energy of the whole two hundred million million globules will be certainly small in comparison with the ultimate average kinetic energy of the single shell. It may be because each globule of § 6 is free to wander that the energy is lost from the shell in that case, and distributed among them. There is nothing vague in their motion allowing them to take more and more energy, now when they are connected by the massless springs. If we suppose the motions infinitesimal, or if, whatever their ranges may be, all forces are in simple proportion to displacements, the elementary dynamical theorem of *fundamental modes* shows how to find determinately each of the 600 million million and six simple harmonic vibrations, of which the motion resulting from the prescribed initial circumstances is constituted. It tells us that the sum of the potential and kinetic energies of each mode remains always of constant value, and that the time-average of the changing kinetic energy during its period is half of this constant value. Without fully solving the problem for the 600 million million and six co-ordinates, it is easy to see that the gravest fundamental mode of the motion actually produced in the prescribed circumstances differs but little in period and energy from the single simple harmonic vibration which the two shells would take if the globules were rigidly connected to them, or were removed from within them, and the other initial circumstances were those of § 6. But this conclusion depends on the forces being *rigorously* in simple proportion to displacements.

(10)[1] In no real case could they be so, and if there is any deviation from the simple proportionality of force to displacement, the independent superposition of motions does not hold good. We have still a theorem of fundamental modes, although, so far as I know, this theory has not yet been investigated. For any stable system moving with a given sum, E, of potential and kinetic energies, there must in general be *at least as many fundamental modes of rigorously periodic motion as there are freedoms* (or independent variables). But the configuration of each fundamental mode is now not *generally* similar for different values of E; and superposition of different fundamental modes, whether with the same or with different values of E, *has now no meaning*. It seems to me probable that every fundamental mode is essentially unstable. It is so if Maxwell's fundamental assumption[1] "that the system, if left to itself in its actual state of motion, will, sooner or later, pass through every phase which is consistent with the equation of energy" is true. It seems to me quite probable that this assumption *is* true, provided the "actual state of motion" is not exactly, as to position and velocity, a configuration of some one of the fundamental modes of rigorously periodic motion, and provided also that the "system" has not any exceptional character, such as those indicated by Maxwell for cases in which he warns[2] us that his assumption does not hold good.

(11) But, conceding Maxwell's fundamental assumption, I do not see in the mathematical workings of his paper[3] any proof of his conclusion "that the average kinetic energy corresponding to any one of the variables is the same for every one of the variables of the system." Indeed, as a general proposition its meaning is not explained, and seems to me inexplicable. The reduction of the kinetic energy to a sum of squares[4] leaves the several parts of the whole with no correspondence to any defined or definable set of independent variables. What, for example, can the meaning of the conclusion[5] be for the case of a jointed pendulum? (a system of two rigid bodies, one supported on a fixed horizontal axis and the other on a parallel axis fixed relatively to the first body, and both acted on only by gravity). The conclusion is quite intelligible, however (but is it true?), when the kinetic energy is expressible as a sum of squares of rates of change of single co-ordinates each multiplied by a function of all, or of some, of the co-ordinates.[6] Consider, for example, the still easier case of these coefficients constant.

(12) Consider more particularly the easiest case of all, motion of a single particle in a plane; that is, the case of just two independent variables, say x, y; and kinetic energy equal to $\frac{1}{2}(\dot{x}^2 + \dot{y}^2)$. The equations of motion are

$$\frac{d^2x}{dt^2} = -\frac{dV}{dx}, \qquad \frac{d^2y}{dt^2} = -\frac{dV}{dy},$$

where V is the potential energy, which may be any function of x, y, subject only to the condition (required for stability) that it is essentially positive (its least value being, for brevity, taken as zero). It is easily proved that, with any given value, E, for the sum of kinetic and potential energies, there are two determinate modes of periodic motion; that is to say, there are two finite closed curves such that, if m be projected from any point of either with velocity equal to $\sqrt{[2(E - V)]}$ in the direction, either-wards, of the tangent to the curve, its path will be exactly that curve. In a very special class of cases there are only two such periodic motions, but it is obvious that there are more than two in other cases.

(13) Take, for example,

$$V = \tfrac{1}{2}(\alpha^2x^2 + \beta^2y^2 + cx^2y^2).$$

For all values of E we have

$$\left.\begin{matrix} x = a\cos(\alpha t - e) \\ y = 0 \end{matrix}\right\} \text{ and } \left.\begin{matrix} y = 0 \\ x = b\cos(\beta t - f) \end{matrix}\right\}$$

as two fundamental modes. When E is infinitely small we have only these two; but for any finite value of E we have clearly an infinite number of fundamental modes, and *every mode* differs infinitely little from being a fundamental mode. To see this, let m be projected from any point N in OX, in a direction perpendicular to OX, with a velocity equal to $\sqrt{(2E - \alpha^2ON^2)}$.

Atlantic. Special floats were thrown into the sea in three different places, and their progress was traced from place to place. As a preliminary trial 160 floats were thrown into the sea between the Azores and the Canary Islands. Some of these arrived at the Bermudas eighteen months later. In all 1700 floats were despatched, and the result was that the great ocean currents of the North Atlantic were now fairly well known. The Prince's new yacht is provided with an electric search-light of 10,000 candle-power for illuminating the surface of the sea when investigations are being carried on at night. Soundings can be made to a depth of 8000 metres without much difficulty. —M. le Baron Jules de Guerne, President of the Zoological Society of France, read a paper on the zoological results of the voyages of the *Hirondelle* (the Prince of Monaco's former yacht). He described the work of exploration among the Oceanic Islands, and alluded specially to the new species which had been found.—Mr. J. Y. Buchanan described a cartographic device which is of great use in the treatment of some geographical and telluric problems.—Mr. W. E. Hoyle described a deep-sea tow-net, which, by means of an electrical device, can be opened and closed at definite (arbitrary) instants.—Dr. H. R. Mill exhibited an improved form of his self-locking water-bottle.

July 20.—The Hon. Lord McLaren in the chair.—Some additional observations, by Prof. McIntosh, on the development and life-histories of the marine food-fishes and the distribution of their ova, were communicated. By means of various kinds of tow-nets, an endeavour has been made to ascertain the distribution of the eggs of the food-fishes on our shores. They are found at all depths, at the surface, and at the bottom. The floating eggs of the pilchard and mackerel are chiefly found on the south and south-west shores. On the east coast of Scotland the ova of the cod, whiting, and haddock are abundant. On the west coast, those of the sole, &c., abound.—The Astronomer-Royal for Scotland read a paper on the bright streaks on the moon. When the moon is half full its brilliancy is not nearly one-half so great as its brilliancy when it is quite full. Now at full moon the surface is observed to be covered by bright streaks which originate at the craters. The author believes that the great brightness of the full moon is due to these streaks. He considers them to be convex or concave, and so to be largely invisible under cross light, while they are brilliantly illuminated when the sun shines full upon them. The paper was illustrated by a model in plaster of Paris, with glass beads attached to its surface.—A paper, by Prof. C. G. Knott, on the effect of longitudinal magnetization on the interior volume of iron and nickel tubes, was communicated.—Dr. H. R. Mill read an obituary notice of Prof. C. I. Burton.

PARIS.

Academy of Sciences, August 3.—M. Duchartre in the chair.—Experimental researches on the probable *rôle* of gases at high temperatures and pressures, and in rapid movement, in various geological phenomena, by M. Daubrée. The experiments show how gases at high pressure, and contained in a closed reservoir, may, by a sort of latent action, violently push out rocks into conical or bell-shaped formations without any noise or escape of gas occurring to indicate their gaseous nature. —Heats of combustion and formation of nitrobenzenes, by MM. Berthelot and Matignon. The heats of combustion of ortho-, meta-, and para-dinitrobenzenes are found to be respectively 704·6, 698·1, and 696·5 calories; and the heats of formation 0·5, 6·8, and 8·4 calories. The heats of combustion of the two isomeric trinitrobenzenes examined are 665·9 and 680·6 calories; and the heats of formation +5·5 and −9·2 calories.—On the oldest European Dicotyledons observed in strata at Cercal, Portugal, by M. G. de Saporta.—On some improvements carried out in the manufacture of artificial Seltzer water: the siphon arrangement, by M. de Pietra Santa.—On a new and improved construction of the thermo-cautery of 1876, by M. Paquelin.—Periodic variations of the latitudes of solar prominences, by M. A. Riccò. The author's observations demonstrate that solar prominences, like spots, approach the equator up to the minimum period of activity, and afterwards begin again to appear more numerous in high latitudes.—On induction inclination needles, by M. Ernest Schéring. This is a brief description of a new magnetic inclination needle constructed by the author, and with which it is said to be possible to determine inclination with a probable error of 4″·2.—On the expansion of phosphorus, and its change of volume at the melting-point, by M. A. Leduc. The coefficient of expansion for solid phosphorus between 0° and 44°·1 is found to be 0·000372, whilst for liquid phosphorus between 26° and 50° the coefficient is 0·000560. The expansion is regular up to the melting-point, but an abrupt change of volume then occurs. The relation between the volume of phosphorus in the liquid and solid state is 1·0345.—Study of the chemical neutralization of acids and bases, by means of their electric conductivities, by M. Daniel Berthelot. From the investigation it appears that, when potash is acted on by hydrochloric acid, acetic acid, and phenic acid, compounds are formed having approximately equal electric conductivities. Ammonia, with the first two acids, gives similar stable salts, but with the last acid an unstable compound having a less electric conductivity is produced. Aniline forms with hydrochloric acid a stable compound having good electrical conductivity; and with acetic acid, an unstable body whose conductivity is said to be mediocre.—Action of phenylhydrazine on phenols, by M. Alphonse Seyewetz.—On the development of sponges (*Spongilla fluviatilis*), by M. Yves Delage.—On *Isaria densa*, Link, a parasite of the white worm, by M. Alfred Giard.—The parasite of the cockchafer, by M. Le Moult.—Action of poisons on the germination of the seeds of the plants which furnish them, by M. Ch. Cornevin.—On the resistance of the rabic virus to the action of prolonged cold, by M. Jobert.—Chromoscopic analysis of white light, by M. A. Charpentier.

Erratum.—On line 36, p. 336, instead of 0·1050 and 4·9720, read 1·1050 and 0·9720.

MACMILLAN & CO.'S PUBLICATIONS.

Crown 8vo, Cloth, 10s. 6d.

LESSONS IN ELEMENTARY BIOLOGY. By T. JEFFREY PARKER, B.Sc., F.R.S., Professor of Biology in the University of Otago, Dunedin, New Zealand. Illustrated.

NATURE:—"An extremely well-written, well-considered, and original class-book. . . . The student will find many of the most important conceptions of biological science set forth and illustrated, not by reference merely to the types which he dissects or examines with greatest ease in the elementary course in a laboratory, but by the use of a larger area of well-chosen examples, both of plants and animals. Original woodcuts, often of exceptional merit, are freely introduced in the text. . . . Its merit, however, consists not merely in the general plan, but in the fact that the author is an experienced teacher and an accomplished investigator, who has developed to a high degree the art of lucid statement—one who is thoroughly familiar with the latest researches in the wide field of which he treats, and is able, whilst setting before his reader the most important generalizations of his science, to avoid redundancy, and to give a fresh and original handling to the oft-told story of the structure and functions of living things."

NEW EDITION OF SIR J. W. DAWSON'S ACADIAN GEOLOGY.

Just Published, Fourth Edition, Royal 8vo, Cloth, 21s.

THE GEOLOGY OF NOVA SCOTIA, NEW BRUNSWICK, AND PRINCE EDWARD ISLAND, or ACADIAN GEOLOGY. By Sir J. WILLIAM DAWSON, LL.D., F.R.S., F.G.S., Principal and Vice-Chancellor of McGill College and University, Montreal. Fourth Edition, with Map, Illustrations, and 2 Supplements.

NEW AND REVISED EDITION OF AIRY'S POPULAR ASTRONOMY.

Just Published, Seventh Edition, Fcap. 8vo, 4s. 6d.

POPULAR ASTRONOMY: a Series of Lectures delivered at Ipswich by Sir GEORGE BIDDELL AIRY, K.C.B., late Astronomer-Royal. Revised by H. H. TURNER, M.A., B.Sc., Chief Assistant, Royal Observatory, Greenwich.

This edition has been very carefully revised by the Chief Assistant of the Royal Observatory, Greenwich, who has, however, introduced no more changes than were absolutely necessary to bring so well-established a book up to date.

BOOKS FOR CHEMICAL STUDENTS.

AUTHORIZED ENGLISH TRANSLATION OF MEYER'S HISTORY OF CHEMISTRY.

8vo, Cloth, 14s. net.

A HISTORY OF CHEMISTRY FROM THE EARLIEST TIMES TO THE PRESENT DAY. Being also an Introduction to the Study of the Science. By ERNST VON MEYER, Ph.D., Professor of Chemistry in the University of Leipzig. Translated with the Author's sanction by GEORGE MCGOWAN, Ph.D., Demonstrator in Chemistry, University College, North Wales, Bangor.

SPEAKER:—"A standard book on the subject. The conclusions are obviously the outcome of wide knowledge, independent research, and sound judgment."

NATURE:—"After carefully reading this work, we can heartily congratulate the author on the success with which he has preserved the 'objective attitude' which is essential to the true historian. . . . For the two chapters which treat of modern chemistry we have nothing but unqualified praise, and we earnestly commend them to the attention of those students who desire to have a *coup d'œil* at once comprehensive and accurate of the meaning and tendency of present-day doctrine."

PROF. OSTWALD'S NEW WORK ON PHYSICAL AND THEORETICAL CHEMISTRY.

Demy 8vo, 10s. net.

OUTLINES OF GENERAL CHEMISTRY. By WILHELM OSTWALD, Professor of Chemistry in the University of Leipzig. Translated, with the Author's sanction, by JAMES WALKER, D.Sc., Ph.D., Assistant in the Chemical Department, University of Edinburgh.

**** *This book is designed to meet the requirements of the student who, while not intending to devote himself to the detailed study of General Chemistry, still wishes to follow intelligibly the progress recently made in this important branch of science. The book has already established itself in Germany as the standard text-book on the subject.*

ACADEMY:—"All these subjects are handled with masterly clearness. The book, moreover, is written in an interesting manner, and we are sure that it will prove an attractive and valuable addition to the library of all students and teachers of chemistry."

A NEW TEXT-BOOK OF CRYSTALLOGRAPHY.

Crown 8vo, Cloth, 6s.

ELEMENTS OF CRYSTALLOGRAPHY FOR STUDENTS OF CHEMISTRY, PHYSICS, AND MINERALOGY. By GEORGE HUNTINGDON WILLIAMS, Ph.D., Assistant Professor in the Johns Hopkins University.

**** *A concise and elementary statement of the general principles of Crystallography, not intended as a complete treatise, but to furnish so much information on the subject as may be of service to students of other but allied branches.*

NATURE:—"We feel assured that the simultaneous publication in this country and in America of so simple and at the same time so accurate a text-book of the subject as the work we are now considering will do much towards reviving and diffusing a taste for the study of crystallography. The student who masters the contents of this little book will undoubtedly have much more to learn before he is competent to deal with all the higher problems of crystallographic science; but, however far his researches may be carried in the future—and this is, perhaps, the very highest praise we can give to the book—he will certainly have little, if anything, to *un*learn."

MACMILLAN & CO.'S PUBLICATIONS.

8vo, Cloth, 14*s.* net.

THE HISTORY OF HUMAN MARRIAGE.

By EDWARD WESTERMARCK, Ph.D.,

Lecturer on Sociology at the University of Helsingfors.

TIMES:—"Very learned and elaborate, scientifically conceived and scientifically executed. It should command the serious attention of all scientific students of sociology."

MANCHESTER GUARDIAN:—"In his introduction to this book Mr. Wallace, than whom there could scarcely be a better authority, says that he has seldom read 'a more thorough or a more philosophic discussion of some of the most difficult and at the same time interesting problems of anthropology.' And a perusal of the book will most assuredly convince the reader that the great naturalist's verdict is fully justified. Mr. Westermarck has established his position among the first of historical anthropologists, he has thrown light upon many of the unsolved mysteries in the history of the human race, and he has swept out of the way several theories which have hitherto blocked the path to a right solution of the main questions at issue. . . . Clearly and becomingly written, based upon a very wide and well-chosen course of reading and investigation, the book affords a model for future investigators in this field."

ANTI-JACOBIN:—"There can be no doubt of the courage of a hitherto unknown student who comes from the comparatively obscure University of Finland to throw down the gauntlet before warriors of such prestige as Darwin, Spencer, Tylor, Lubbock, and McLennan; but intelligent students of Mr. Westermarck's volume will acquit him of temerity, and, indeed, it is more than possible that, as Mr. Alfred Wallace predicts in his introduction, 'the verdict of independent thinkers will be in favour of the newcomer.' . . . . A book which is far too rich in the detailed products of laborious research to be treated at once briefly and adequately. It is certainly the most valuable of recent contributions to the literature of a deeply-interesting theme; and not the least of its recommendations is that, while it necessarily deals with many delicate topics, the handling is absolutely reproachless on the score of taste."

LIVERPOOL DAILY POST:—"Since the appearance of Mr. McLennan's work on 'Primitive Marriage' there has been no study of the manners and habits of savage races that in point of originality can compete with Mr. Westermarck's 'History of Human Marriage.' . . . There is every reason to suppose that this deeply interesting book will find a host of readers even among those who are attracted by facts for their own sake rather than for the theories that may be drawn from them."

NEW VOLUME OF NATURE SERIES.

Just ready, 8vo, Cloth, 4*s.* 6*d.*

THE RIGHT HAND: LEFT HANDEDNESS. By Sir DANIEL WILSON, LL.D., F.R.S.E., President of the University of Toronto.

Just ready, 8vo, Cloth, 12*s.* net.

THE POSITIVE THEORY OF CAPITAL. By EUGEN V. BÖHM-BAWERK, Counsellor in the Austrian Ministry of Finance, and Honorary Professor of Political Economy in the University of Vienna. Translated, with a Preface and Analysis, by WILLIAM SMART, M.A., Lecturer on Political Economy in Queen Margaret College, Glasgow.

This volume, in which the author sets forth his own theory of Capital, is the sequel and complement of the volume on "Capital and Interest," treated historically and critically, which was published in England some months ago, and was very cordially received by English Economists.

TIMES:—"Mr. Smart has done his work excellently. His preface, analytical digest, and the actual translation are all admirable. We have to thank him for rendering accessible to English students a treatise which is certainly well worth attention as a specimen of contemporary Continental thought, and which, although its central theory is based, as the author frankly avows, upon certain ideas of Jevons, has carried those ideas further and given them a special application."

UNIFORM WITH THE ABOVE.

8vo. Price reduced to 12*s.* net.

CAPITAL AND INTEREST: a Critical History of Economical Theory. By EUGEN V. BÖHM-BAWERK, Honorary Professor of Political Economy in the University of Vienna. Translated, with a Preface and Analysis, by WILLIAM SMART, M.A., Lecturer on Political Economy in Queen Margaret College, Glasgow.

NEW EDITION, REVISED.

Crown 8vo, Cloth, 10*s.* 6*d.*

A COURSE OF PRACTICAL INSTRUCTION IN BOTANY. By F. O. BOWER, D.Sc., F.R.S., Regius Professor of Botany, Glasgow.

NATURE:—"Everyone perusing the volume must be impressed with the high standard of its educational value. Teacher and student in this country are alike to be congratulated upon its publication."

ACADEMY:—"The work is one which should be in the hands of every practical botanist."

SATURDAY REVIEW:—"The types are good, easily obtained, and thoroughly worked out. . . . There is no padding, the text is to the point, and it assumes the presence of the plant concerned and the instruments in hand. We regard the absence of illustrations and of descriptive padding as important preventives of cram, and it should be clearly borne in mind that laboratory teaching suffers especially by the opening up of royal roads."

BY SIR ARCHIBALD GEIKIE, LL.D., F.R.S.

New and Revised Edition. Globe 8vo, 3*s.* 6*d.*

OUTLINES OF FIELD GEOLOGY. By Sir ARCHIBALD GEIKIE, LL.D., F.R.S., Director-General of the Geological Survey of Great Britain and Ireland.

"*This volume has now been thoroughly revised and considerably enlarged. One of the chief changes will be found in the account of the schistous rocks, which has been re-written in the light of recent researches into these interesting but difficult parts of the geological record. A number of new illustrations have been added from my note-books.*"—From the Author's Preface.

LONDON UNIVERSITY EXAMS.

UNIV. CORR. COLL. TUTORIAL SERIES.

MATRICULATION.

MATRICULATION DIRECTORY, with FULL ANSWERS to the Examination Papers. No. X., June 1891. Cloth Gilt, **1s.**

Latin Composition and Syntax. With copious Exercises. By A. H. ALLCROFT, M.A. Oxon., and J. H. HAYDON, M.A. Camb. and Lond. **2s. 6d.** KEY, **2s. 6d.**
The Book-work deals with Latin Syntax fully enough to be used as a Text-book on the subject, and the relative importance of rules and exceptions is shown by variety of type. Each Exercise is divided into three sections of progressive difficulty.

London Undergraduate Unseens: A Reprint of all the Latin and Greek Passages set at Matric. and Inter. Arts, 1875–1890. Second Edition. **1s. 6d.**

Matriculation Latin. By B. J. HAYES, M.A. Lond. Third Edition, Enlarged. **1s 6d.**
CONTENTS:—Choice of Text-books—Weekly Schemes of Study, with Notes and Hints—Matric. Papers in Latin Grammar—Illustrative Sentences for Latin Prose, &c.

Matriculation and Intermediate Greek. By J. B HAYES, M.A. Lond., and W. F. MASOM, M.A. Lond. **2s. 6d.**

French Prose Reader. By S. BARLET, B.-ès-Sc., and W. F. MASOM, M.A. Lond. **1s. 6d.**

Matriculation Mathematics. Fourth Edition. **1s. 6d.**

Elementary Text-book of Heat and Light. By R. W. STEWART, B.Sc. Lond. **3s. 6d.**

Heat and Light Problems, with numerous Worked Examples. By R. W. STEWART, B.Sc. Lond. **1s. 6d.**

Matriculation Greek Papers: a Reprint of the last Thirty Papers in Greek set at Matriculation; with Model Answers to the Paper of January 1890. By B. J. HAYES, M.A. Lond., and W. F. MASOM, M.A. Lond. **1s.**; Cloth Gilt, **1s. 6d.**

Matriculation French Papers. 1s.; Cloth Gilt. **1s. 6d.**

Matriculation English Language Papers. **1s.**; Cloth Gilt. **1s. 6d.**

Matriculation English History Papers. 1s.; Cloth Gilt, **1s. 6d.**

Registered as a Newspaper at the General Post Office.]

[All Rights are Reserved.

THE NEW PATENT WATKIN ANEROID BAROMETER.

PRICES FROM £3 to £7. ALSO MADE WATCH SIZE.

Amongst many unsolicited Testimonials the following has been received by the maker:—

EDINBURGH, May 31, 1889.

DEAR SIR.—I have just returned from a six weeks' stay at the Ben Nevis Observatory, and while there had an opportunity of testing the admirable qualities of your new "Watkin" Aneroid. The result has been most satisfactory, the extreme error noted being only about $\frac{1}{100}$ of an inch. During my stay at the Observatory the Aneroid was frequently tested by taking it down 2000 feet and then comparing it with the standard on my return. The results obtained speak volumes for the high class workmanship and great accuracy you have attained in the manufacture of this instrument.

(Signed) R. C. MOSSMAN, F.R.M.S., Observer, Scott. Met. Soc.

To be obtained of all Opticians and Wholesale Houses.

J. J. HICKS, 8, 9, & 10 HATTON GARDEN, LONDON.

"The 'STAR' MICROSCOPE is a modern marvel at its low price The lenses alone are worth the money."—*British Medical Journal.*

BECK'S

£2 2s. to £5 5s.

NEW MODEL "STAR" MICROSCOPE

It is made throughout in brass, neatly japanned, and is not only first-rate in optical qualities, but is now a handsome, well-finished Instrument.

R. & J. BECK, 68 Cornhill, London, E.C.

UNIVERSITY COLLEGE, LONDON.

LECTURES ON ZOOLOGY.

Prof. W. F. R. WELDON, M.A., F.R.S., will deliver during the ensuing Session a Course of Lectures on the DECAPOD CRUSTACEA, intended specially for Senior Students who intend to pursue original investigations in Zoology. The Lectures will be given twice weekly, commencing SATURDAY, OCTOBER 17, at 10 a.m.

The General Course of Lectures on Zoology, suitable for Students preparing for the various Examinations of the University of London, commences MONDAY, OCTOBER 5, at 4 p.m.

UNIVERSITY COLLEGE, LONDON.

The Session of the Faculty of Medicine will commence on OCTOBER 1. Introductory Lecture at 4 p.m., by Prof. VICTOR HORSLEY, M.B., B.S., F.R.S., Assistant Surgeon to University College Hospital.

The Examinations for the Entrance Exhibitions will commence on SEPTEMBER 23.

Scholarships, Exhibitions, and Prizes of the value of £800 are awarded annually.

In University College Hospital about 3000 In-patients and 35,000 Out-patients are treated during the year. Thirty-six appointments, eighteen being resident, as House Surgeon, House Physician, Obstetric Assistant, &c., are filled up by competition during the year, and these, as well as all Clerkships and Dresserships, are open to Students of the Hospital without extra fee.

Prospectuses, with full information as to Classes, Prizes, &c., may be obtained from the College, Gower Street, W.C.

E. A. SCHÄFER, F.R.S., Dean.
J. M. HORSBURGH, M.A., Secretary.

THE VICTORIA UNIVERSITY.

The following Examinations will be held at OWENS COLLEGE (MANCHESTER), UNIVERSITY COLLEGE (LIVERPOOL), and YORKSHIRE COLLEGE (LEEDS), in SEPTEMBER.

AN ENTRANCE EXAMINATION IN ARTS (introductory to the Faculty of Medicine) on FRIDAY, September 25, and following days.

AN ENTRANCE EXAMINATION IN ARTS (introductory to the Faculty of Music) on FRIDAY, September 25, and following days.

A PRELIMINARY EXAMINATION (introductory to the Faculties of Arts, Science, and Law) on THURSDAY, September 24, and following days.

Notice (*in writing*) of intention to be present, accompanied with a List of the subjects taken, must be sent, on or before September 9, to the UNIVERSITY REGISTRAR, from whom Conditions of Entrance, and other Particulars can be obtained.

Fees for the above Examinations must be paid on or before September 14.

Manchester, August 1891.

OWENS COLLEGE, VICTORIA UNIVERSITY, MANCHESTER.

PROSPECTUSES for the SESSION 1891-92 will be forwarded on application.

I.—DEPARTMENT of ARTS, SCIENCE, and LAW.
II.—DEPARTMENT of MEDICINE.
III.—DENTAL DEPARTMENT.
IV.—PHARMACEUTICAL DEPARTMENT.
V.—DEPARTMENT for WOMEN.
VI.—DEPARTMENT of the EVENING CLASS.
VII.—SCHOLARSHIPS, EXHIBITIONS, &c. (varying in value from £12 to £100 per annum).

Apply to Mr. CORNISH, 16 St. Ann's Square, Manchester; or at the College.

HENRY WM. HOLDER, M.A., Registrar.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF.

The Council of the University College of South Wales and Monmouthshire is prepared to appoint a PROFESSOR OF MINING. The Stipend of the Professor will be £350 per Annum

Applications, together with Testimonials and References, should be forwarded on or before TUESDAY, SEPTEMBER 15, 1891.

For further information, apply to

IVOR JAMES, Registrar.

Cardiff, August 12, 1891.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF.

The Council of the University College of South Wales and Monmouthshire is prepared to appoint a LECTURER in GEOLOGY. The Stipend of the Lecturer will be £200 per Annum.

Applications, together with Testimonials and References, should be forwarded on or before TUESDAY, SEPTEMBER 15, 1891.

For further information apply to

IVOR JAMES, Registrar.

Cardiff, August 12, 1891.

LIVING SPECIMENS FOR THE MICROSCOPE.

Gonium pectorale, Volvox globator, Melicerta ringens, Plumatella repens, Paludicella Ehrenbergi, and other beautiful specimens of Pond-life, 1s. per Tube, with Drawing and Description. Amœba, &c., for Students of Biology.

List Post Free.

THOMAS E. BOLTON,
FARLEY ROAD, MALVERN LINK.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF.

COUNTY OF GLAMORGAN.

The Council of the University College of South Wales and Monmouthshire is prepared to appoint the following Members of a Staff of Travelling Teachers in Technical Subjects for the County of Glamorgan:—

A Lecturer in Mathematics and Theoretical Mechanics.
A Lecturer in Chemistry and Metallurgy.
A Lecturer in Geology and Mining.
One or Two Lecturers in Mechanical Engineering.

The Stipend of each Lecturer will be £200 per Annum, together with travelling expenses.

Applications, together with Testimonials and References, should be sent in not later than TUESDAY, SEPTEMBER 8, 1891, to the undersigned, from whom further information in regard to the duties of the Staff may be obtained.

IVOR JAMES, Registrar.

Cardiff, August 12, 1891.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF.

COUNTY OF MONMOUTH.

The Council of the University College of South Wales and Monmouthshire is prepared to appoint a Director of the Staff of Travelling Teachers in Technical Subjects, to be established under the provisions of the scheme of the Technical Instruction Committee of the County of Monmouth. The Stipend of the Director will be £350 per Annum.

Candidates for the post must send in their Applications, together with Testimonials and References, to the undersigned, on or before TUESDAY, SEPTEMBER 8, 1891.

For further information and for Copies of the above Scheme, apply to

IVOR JAMES, Registrar.

Cardiff, August 12, 1891.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF.

The CHAIR of GREEK is now Vacant through the Election of Prof. ROBERTS as Principal of the University College, Aberystwyth. The Council will proceed to the Appointment of the new Professor in September Next. The Stipend of the Professor will be £350 per Annum.

Applications, together with Testimonials and References, should be forwarded before TUESDAY, SEPTEMBER 8, 1891.

For further Information apply to

IVOR JAMES, Registrar.

Cardiff, August 4, 1891.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF.

The DEPARTMENTS OF ARTS, SCIENCE, AND ENGINEERING, and the NORMAL DEPARTMENTS FOR INTERMEDIATE AND ELEMENTARY TEACHERS, will open on MONDAY, OCTOBER 5, 1891. The Lectures and Classes are open to Men and Women.

For Prospectus, and information concerning Scholarships, &c., apply to

IVOR JAMES, Registrar.

University College, Cardiff, August 11, 1891.

FIRTH COLLEGE, SHEFFIELD.

The Council of Firth College propose to appoint an ASSISTANT DEMONSTRATOR IN CHEMISTRY, at a Salary of £100.

Session—OCTOBER to JUNE.

Applications must be sent, before SEPTEMBER 12, to the REGISTRAR, from whom further particulars may be obtained.

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR.

(Incorporated under Royal Charter. Departments: Arts, Science, Agriculture.)

AGRICULTURAL DEPARTMENT.

A complete Course of Instruction in Agriculture and Dairying has now been organized.

Full information about College Classes, Scholarships, Diplomas in Agriculture, Certificates in Dairying, &c., will be found in the Agricultural Prospectus (free on application).

The average cost of living in Bangor, including College fees, is about £40 for the College year.

The Next Session begins on SEPTEMBER 29, 1891.

W. CADWALADR DAVIES, Secretary and Registrar.

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR.

AGRICULTURAL DEPARTMENT.

An ASSISTANT LECTURER in AGRICULTURE will be appointed in SEPTEMBER next, for one year, at a Salary of £120.

Applications must be sent in on or before SATURDAY, SEPTEMBER 5, to the undersigned, from whom information as to conditions of Appointment and Duties may be obtained.

W. CADWALADR DAVIES, Secretary and Registrar.

University College of North Wales, Bangor,
July 1, 1891.

UNIVERSITY COLLEGE, NOTTINGHAM,

ENGINEERING DEPARTMENT.

Professor, WILLIAM ROBINSON, M.E., Assoc. M. Inst. C.E.,

Session 1891–92 begins on MONDAY, OCTOBER 5

Courses of Technical Instruction extending over three years are arranged for boys who have just left school and intend to take up Electrical, Mechanical, or Civil Engineering. These include Drawing Office, Laboratory and Workshop Practice, and Classes in Engineering, Mathematics, Physics, Chemistry, and Metallurgy.

The Mechanical Workshops are completely equipped with tools both in wood and iron, also forge and foundry. Instructors give special attention to Students in the various branches of Mechanical Engineering. Special facilities are offered to Students in Electrical Engineering—Electrical Laboratories including New Dynamo Room with Phœnix Dynamo, driven by Atkinson Cycle Gas-Engine, and specially fitted for Experimental Purposes. Technical Instruction in Electric and Magnetic Measurements, Dynamo-testing, &c., and Students take charge of Brush-Lighting Dynamo, trim Arc Lamps, &c., &c.

Several Scholarships and Exhibitions are offered.

For Prospectus and Fees (which are exceptionally low) apply to the SECRETARY.

GUY'S HOSPITAL MEDICAL SCHOOL.

The WINTER SESSION begins on THURSDAY, OCTOBER 1.

The Hospital contains 695 Beds, of which 500 are in constant occupation. Special Classes are held for the M.B. Camb. and Lond., the F.R.C.S. Eng., and other Higher Examinations.

APPOINTMENTS.—All Hospital Appointments are made in accordance with the merits of the Candidates, and without extra payment.

ENTRANCE SCHOLARSHIPS in September 1891.—Two Open Scholarships in Arts, one of the Value of 100 Guineas, open to Candidates under 20 Years of Age; and one of 50 Guineas, open to Candidates under 25 Years of Age. Two Open Scholarships in Science, one of the Value of 125 Guineas, and another of 50 Guineas, open to Candidates under 25 Years of Age.

PRIZES are awarded to Students in their various years, amounting in the aggregate to more than £450.

DENTAL SCHOOL.—A Dental School attached to the Hospital affords to Students all the instruction required for a Licence in Dental Surgery.

COLLEGE.—The Residential College accommodates about Fifty Students in addition to the Resident Staff of the Hospital. There is in it a large Dining Hall, with Reading Rooms, Library, and Gymnasium for the use of the STUDENTS' CLUB.

For Prospectus and further information apply to the Dean, Dr. PERRY, Guy's Hospital, London, S.E.

THE AGRICULTURAL COLLEGE, ASPATRIA.

PRINCIPAL—DR. H. J. WEBB, B.Sc.

Thorough practical and scientific Training in Agriculture. Preparation for the Colonies. Students gained the First, Third, and Fourth Scholarships of the Royal Agricultural Society, 1888; First in Agriculture Junior Scholarships, 1889; First in Agriculture Senior Scholarships, 1890

DULWICH COLLEGE, S.E.

Applications are invited for the appointment of DEMONSTRATOR in the Mechanical Laboratory, and INSTRUCTOR in Mechanical Drawing. Salary £130 per annum, with prospect of increase.

Apply, with Copies of Testimonials, to

F. W. SANDERSON.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL,

ALBERT EMBANKMENT, LONDON, S.E.

The WINTER SESSION of 1891–92 will open on THURSDAY, OCTOBER 1, when the Prizes will be distributed at 3 p.m. by Sir G. M. HUMPHRY, M.D., LL.D., F.R.S.

TWO ENTRANCE SCIENCE SCHOLARSHIPS of 125 guineas and £60 respectively, open to all first-year Students, will be offered for competition. The Examination will be held on September 26, 28, and 29, and the subjects will be Chemistry and Physics, with either Physiology, Botany, or Zoology, at the option of Candidates.

Scholarships and Money Prizes of considerable value are awarded at the Sessional Examinations, as also several Medals.

Special Classes are held throughout the year for the Preliminary Scientific and Intermediate M.B. Examinations of the University of London.

All Hospital Appointments are open to Students without charge.

The Fees may be paid in one sum or by instalments. Entries may be made separately to Lectures or to Hospital Practice, and special arrangements are made for Students entering in their second or subsequent years; also for Dental Students and for Qualified Practitioners.

A Register of approved Lodgings is kept by the Medical Secretary, who also has a List of local Medical Practitioners, Clergymen, and others who receive Students into their houses.

Prospectuses and all particulars may be obtained from the Medical Secretary, Mr. GEORGE RENDLE.

G. H. MAKINS, Dean.

BOHN'S LIBRARIES.

This Series now contains **786** *Volumes, Published with a few exceptions at* **3s. 6d.** *or* **5s.** *each. Among the Subjects included the following may be mentioned:—*

STANDARD WORKS on History, Biography, Topography, Archæology, Theology, Antiquities, Science, Philosophy, Natural History, Poetry, Art, Fiction, &c.

DICTIONARIES & OTHER REFERENCE BOOKS.

COMPLETE EDITIONS OF THE ENGLISH CLASSICS; and

TRANSLATIONS of Standard Works from the French, German, Italian, Spanish, Portuguese, and other languages; of the Latin and Anglo Saxon Chroniclers; and of all the chief Greek and Latin Classic Authors.

A SELECTED LIST OF SCIENTIFIC AND PHILOSOPHICAL BOOKS.

A MANUAL OF THE HISTORY OF PHILOSOPHY, for the use of Students. By E. BELFORT BAX, Editor of Kant's "Prolegomena." 5*s*.

COMTE'S PHILOSOPHY OF THE SCIENCES, being an Exposition of the Principles of the *Cours de Philosophie Positive*. By G. H. LEWES, Author of "The Life of Goethe," "Biographical History of Philosophy," &c. With Index. 5*s*.

MONTESQUIEU'S SPIRIT OF LAWS. A New Edition, revised and corrected, with D'Alembert's Analysis, Additional Notes, and a Memoir, by J. V. PRITCHARD, A.M. 2 vols. 7*s*.

RICARDO ON THE PRINCIPLES OF POLITICAL ECONOMY AND TAXATION. Edited by E. C. K. GONNER, M.A., Lecturer, University College, Liverpool. 3*s*. 6*d*.

SMITH (Adam). THE WEALTH OF NATIONS. AN INQUIRY INTO THE NATURE AND CAUSES OF Edited by E. BELFORT BAX. 2 vols. 7*s*.

HUMBOLDT'S COSMOS; or, Sketch of a Physical Description of the Universe. Translated by E. C. OTTÉ, B. H. PAUL, and W. S. DALLAS, F.L.S. With Portrait. 5 vols. 3*s*. 6*d*. each, excepting Vol. V. 5*s*.

*** In this edition the notes are placed beneath the text. Humboldt's analytical Summaries and the passages hitherto suppressed are included; and new and comprehensive Indexes are added.

HUMBOLDT'S PERSONAL NARRATIVE of his Travels to the Equinoctial Regions of America during the years 1799–1804 Translated from the French and Edited, with Notes and Index, by T. ROSS. 3 vols. 5*s*. each.

HUMBOLDT'S VIEWS OF NATURE; or, Contemplations of the Sublime Phenomena of Creation, with Scientific Illustrations. Translated by E. C. OTTÉ and H. G. BOHN. With a Fac-simile Letter from the Author, Translations of the Quotations, and a very complete Index. 5*s*.

CHEVREUL ON COLOUR. Containing the Principles of Harmony and Contrast of Colours, and their Application to the Arts. Translated by CHARLES MARTEL. Third and only complete edition, with Introduction by the Translator. With Index and Coloured Plates. 7*s*. 6*d*.

By A. J. JUKES-BROWNE, B.A., F.G.S., of the Geological Survey of England and Wales.

STUDENT'S HANDBOOK OF PHYSICAL GEOLOGY. With numerous Diagrams and Illustrations. 6*s*.

"Should be in the hands of every teacher of Geology."—*Journal of Education.*

"A very useful book dealing with geology from its physical side."—*Athenæum.*

STUDENT'S HANDBOOK OF HISTORICAL GEOLOGY. With numerous Diagrams and Illustrations. 6*s*.

"Mr. Jukes-Browne is to be congratulated on having, with this volume, brought his work to so satisfactory a conclusion."—*Athenæum.*

"An admirably planned and well executed 'Handbook of Historical Geology.'"—*Journal of Education.*

THE BUILDING OF THE BRITISH ISLES. A Study in Geographical Evolution. With Maps. 7*s*. 6*d*.

[*New edition preparing.*

"We have followed Mr. Jukes-Browne with much pleasure through this very interesting study in geographical evolution, and can strongly recommend it to the attention of all geologists and physical geographers. . . . . What is specially to be commended in this book is its freedom from any extravagant ideas: the author has taken for his motto, '*In medio tutissimus ibis*,' and in this spirit has acted throughout."—*Geological Magazine.*

THURSDAY, AUGUST 20, 1891.

THE CONGRESS OF HYGIENE.

THE proceedings of this Congress were brought to a close on Monday, it being generally conceded that the importance of the conclusions arrived at and of the discussions on the more important topics were on a level with the numbers and eminence of the men of science taking part in the deliberations.

So far as space permits, we shall endeavour to give an account of some of the most salient subjects touched in the different Sections. To get a general idea of the enormous area of the ground covered, it is only necessary to glance at the resolutions adopted. It will be generally conceded that the members of the Congress are by these resolutions supplied with much food for thought in the interim which will elapse till the next meeting, which has been fixed at Budapest and for 1894.

We note with the greatest pleasure that Her Majesty and the University of Cambridge have shown their appreciation of the honour done to the nation by the presence of so many foreigners; and that other bodies and individuals have not been lacking to render possible gatherings of a less severely scientific character than the Sectional meetings.

Her Majesty's action in inviting many of the most eminent representatives of different nationalities to Osborne—an action, we believe, suggested by the Prince of Wales—has been so well received, that one regrets that the nation has had to wait so long for such a precedent. We regret it, not so much for the sake of men of science, but because the result has been that Royalty here has always lived apart not only from science but from national culture generally. The Queen, indeed, on the present system, never need know anything, except by some happy accident, of Britain's greatest men.

The party which went to Osborne left early by a special train, and were taken over from Portsmouth in the Queen's yacht. They were accompanied by Sir D. Galton, Dr. Poore, Prof. Corfield, and Mr. S. Digby. Luncheon was provided at 2, and Her Majesty later on received the visitors, of whom the following is an official list:—

Austria-Hungary.—Dr. Emil Kusý, Ministerialrath, Sanitats referent, delegated by Minister of the Interior; Hofrath Franz Ritter von Gruber, Professor of Architecture, elegated by Imperial Council of Health; Dr. Ernst Hofrath Ludwig, Professor of Applied Chemistry at Pathological Institute, delegated by Minister of Finance; Dr. J. Fodor, Professor of Hygiene, University of Budapest, delegated by Minister of Public Worship and Education.

Belgium.—M. E. Beco, Secretary-General of the Department of Agriculture, Industry, and Public Works, delegated by Minister of Agriculture and Public Works; D. E. Janssens, Inspecteur en chef de l'Hygiène à Bruxelles, Membre de la Commission Centrale de Statistique de Belgique, de l'Académie Royale de Médecine et du Conseil Supérieur d'Hygiène.

Denmark.—Dr. J. Lehmann, Dean of the Royal Sanitary Council, delegated by the Danish Government; Hans V. Berg, Medical Director of the Navy, delegated by Danish Naval Department; Sur.-Col. Laub, delegated by the Danish Army Department.

Egypt.—Dr. Hassan Pasha Ibrahim, Inspector Sanitary Department, and Professor of Hygiene.

France.—Dr. Etienne Jules Bergeron, Secrétaire perpétuel de l'Académie de Médecine, Vice-Président du Comité Consultatif d'Hygiène Publique, delegated by Ministry of Public Instruction M. le Dr. Brouardel, Doyen de la Faculté de Médecine de Paris, Président du Comité Consultatif d'Hygiène Publique, delegated by French Government; M. le Dr. Auguste Chauveau, Membre de l'Institut, delegated by the Ministry of the Interior, of Public Instruction, and of Agriculture; M. le Dr. Béranger Féraud, Président du Conseil Supérieur de la Marine, delegated by the French Government; Dr. Levraud, Président du Conseil Municipal de la Ville de Paris, delegate of City of Paris; M. Roux, Pasteur Institute, Paris.

Germany.—Dr. Büchner, Professor at Munich University, delegated by the Bavarian Government; Dr. von Coler, delegated by the Army Medical Department, Prussian Army; Prof. Sell, Geheimrath, delegated by the German Empire; Dr. Pistor, Geheim Medicinalrath, delegated by the Prussian Government; Prof. Dr. W. Roth, President of German Committee of the International Congress, Generalarzt des XII. K. S. Armée Corps, delegated by War Ministry of Saxony; Prof. von Koch, delegate of Government of Würtemberg.

Italy.—Dr. Angelo Mosso, Professor at Royal University, Turin, delegated by Italian Government; Dr. A. Corradi, Professor at Royal University, Pavia, delegated by Italian Government.

Japan.—Dr. Shimpei Gotoh, Official Expert in Ministry of Interior, Tokio, delegated by the Government of Japan.

The Netherlands.—Dr. G. van Overbeek de Meyer, Professor of State University, Utrecht, delegate of Government; Dr. W. P. Ruysch, Conseillier pour le Service Sanitaire, Department de l'Intérieur, delegated by Government of the Netherlands.

Roumania.—Dr. J. Felix, Professeur Université de Bucarest, Membre du Conseil Sanitaire Supérieure de Roumanie, Membre en chef de la Ville de Bucarest, delegated by Government of Roumania and City of Bucharest.

Russia.—Prof. Constantin Kowalkowski, Professeur d'Hygiène à l'Université Impériale de Varsovie, delegated by Imperial University, Warsaw.

Spain.—Don Juan Vilanova y Piera, President of Health Section of Royal Academy of Medicine, delegated by Spanish Government.

Sweden and Norway.—Dr. Linroth, Chief Medical Officer, Stockholm, delegated by Swedish Government and by City of Stockholm; Dr. Gotfried E. Bentzen, Director of the Civil Medical Service, Christiana, delegated by Government of Sweden and Norway.

Servia.—Dr. Georgevitch, delegated by Servian Government.

Switzerland.—Dr. Guillaume, Director of the Federal Bureau of Statistics, delegate of the Swiss Government; Col. Dr. Göldlin de Tiefenau, Instructeur en chef des Troupes Sanitaires Suisses, delegate of the Swiss Government.

United States of North America.—Major Alfred Woodhull, Medical Department, United States Army, delegated by United States Government Army Department; Lieut.-Col. Philip S. Wales, Medical Director United States Navy, delegated by United States Government Naval Department; Dr. Salmon, Chief of Bureau of Animal Industry in the United States Department of Agriculture, delegated by Department of Agriculture.

India.—Dr. Simpson, Sanitary Officer of Calcutta; Mancherjee Bhownaggree, C.I.S., member of the Bhavnagar Judicial Council, delegate of Maharajah of Bhavnagar; Dr. Prasanna Kimar Ray, Professor at Presidency College, delegated by Chancellor and Syndicate of Calcutta University.

Ceylon.—Dr. Solomon Fernando, delegate of Government of Ceylon, and of Medical College.

Canada.—Dr. Covernton, delegated by Ontario, Canada.

New South Wales.—Dr. J. Ashburton Thompson, delegated by Government of New South Wales.

Victoria.—Dr. Aubrey Bowen, delegated by Government of Victoria.

The visit to Cambridge took place on Saturday. The University authorities did all in their power to make it an agreeable one. Not only did hospitality abound, but even in the Long Vacation degrees were conferred (this, unfortunately, is impossible at Oxford) on Drs. Brouardel, Corradi, and Fodor.

The speeches made by the Public Orator were as follows:—

Digitized by Google

DIGNISSIME domine, domine Procancellarie, et tota Academia:—

Nescio quo potissimum exordio hospites nostros, qui de salute publica nuper deliberaverunt, senatus nomine salutare debeam. Ad ipsos conversus, illud unum dixerim:—qui aliorum saluti tam praeclare consuluistis, vosmetipsos omnes iubemus salvere. Ea vero studia, quae vobis cordi sunt, gloriamur in Britannia certe Academiam nostram primam omnium adiuvisse. In salutis publicae ministris nominandis valent plurimum diplomata nostra, valent etiam aliarum Academiarum, quae, exemplo nostro incitatae, laudis cursum eundem sunt ingressae. Hodie vero collegarum vestrorum nonnullos, qui gentium exterarum inter lumina numerantur, diplomate nostro honorifico decorare volumus. Nemini autem mirum sit, quod viros medicinae in scientia illustres iuris potissimum doctores hodie nominamus. Etenim Tullium ipsum in libris quos de Legibus composuit, scripsisse recordamini populi salutem supremam esse legem.

(1) Primum omnium vobis praesento gentis vicinae, gentis nobiscum libertatis bene temperatae amore coniunctæ civem egregium, Parisiorum in Academia medicinae forensis professorem praeclarum, facultatis medicae decanum dignissimum, salutis denique publicae annalium editorem indefessum. Olim Caesar omnes medicinam Romae professos civitate donavit; nos non omnes certe, sed, habito delectu aliquo, unum e reipublicae Gallicae medicis illustrissimis, qui admirabilem in modum medicinae et iuris studia consociavit, corona nostra ob cives etiam in pace servatos libenter coronamus.

Duco ad vos PAULUM CAMILLUM HIPPOLYTUM BROUARDEL.

(2) Quo maiore dolore Austriae et Germaniae legatos illustres absentes desideramus, eo maiore gaudio Italiae legatum insignem praesentem salutamus. Salutamus Academiae Bononiensis, nobiscum vetere hospitii iure coniunctae, alumnum, tribus deinceps in Academiis, primum Mutinae, deinde Panormi, denique Ticini in ripa professorem, qui medicinae scientiam cum rerum antiquitus gestarum studiis feliciter consociavit, quique in Italiae scriptoribus eximiis, non modo in Boccaccio sed etiam in Torquato Tasso, artis suae argumenta non indigna invenit. Quondam imperator quidam Romanus Roma in ipsa augurium salutis per annos complures omissum repeti ac deinde continuari iussit. Quod autem salutis publicae concilio Londinensi etiam Italia interfuit, velut augurii felicis omen accipimus. Recordamur denique poetam antiquum urbis aeternae de nomine his fere verbis non inepte esse gloriatum:—

> Roma ante Romulum fuit;
> non ille nomen indidit,
> "sed diva flava et candida,
> Roma, Aesculapi filia." [1]

Duco ad vos Aesculapi ministrum fidelissimum, ALPHONSUM CORRADI.

(3) Quis nescit urbem florentissimam quod Hungariae caput est, nomine bilingui nuncupatam, fluminis Danubii in utraque ripa esse positam. Quis non inde nobis feliciter advectum esse gaudet salutis publicae professorem insignem, virum titulis plurimis cumulatum, qui etiam de Angliae salubritate opus egregium conscripsit. Idem, velut alter Hippocrates, de aëre, aquis et locis praeclare disseruit. Olim Hippocrates ipse corona aurea Atheniensium in theatro donatus est: nos Hippocratis aemulum illustrem laurea nostra qualicunque in hoc templo honoris libenter ornamus.

Duco ad vos bacteriologiae cultorem acerrimum, IOSEPHUM DE FODOR.

The final general meeting of the Congress was held on Monday, under the presidency of Sir Douglas Galton. There was a large attendance, and among those present were nearly all the foreign delegates.

The Chairman, in opening the proceedings, after some preliminary remarks, said:—The success of the Congress, as an international gathering, is due to the fact that we as a nation have many matters of interest to show to foreigners. I think I may say that the chief difference between our hygienic progress and that of our Continental neighbours is that, whilst they are especially fortunate in being able to pursue the theories upon which much of modern hygienic progress is based, with us public opinion has hindered the study of many physiological questions, the solution of which depends upon the examination of living tissue. Hence, we at present are in this respect somewhat behind the Continental schools, and we largely turn our attention to apply their theories to alleviate the wants of life. Hence we can show much of interest in practical hygiene in matters both of construction and administration. Our methods of water supply and drainage, our various plans for refuse disposal or utilization, our isolation hospitals and ambulance systems present many interesting features. The arrangements which are being made to introduce sanitary knowledge and efficiency of workmanship in trades (such as the plumber), upon whom the practical sanitation of parts of our houses largely depends, are deserving of consideration; and the health administrations of the large cities of Glasgow and Manchester is especially worthy of the study of our visitors. The organization of this Congress has differed from that of former Congresses in the increased number of Sections into which it was divided. In proportion as the study of hygiene and demography becomes more elaborate, the classification must necessarily be more detailed, and the number of Sections must either gradually increase or the Sections must subdivide. Independently of the increased number of Sections, it was found necessary to give two afternoons to the discussion of questions connected with the sanitation of our Indian Empire, which, for the first time in the history of these Congresses, was represented by a large number of delegates. The native Princes of India evinced deep sympathy with the Congress, and I trust that the interest which has been evoked in its object may lead to beneficial results in that great country. . . . A principal object of the Congress is, without doubt, to afford to scientific men in different countries the opportunity of conferring together. But it has another and most important object—viz. to excite the interest of the community at large in the knowledge of the laws of health. Your President the other day asked the pertinent question—Why, if diseases are preventable, are they not prevented? The answer to that question is that, whilst an instructed minority may understand the importance of observing hygienic laws, a very large section of the community is careless of and indifferent to their observance, and consequently the portions of those laws which are individual and personal in their application are left a dead letter. Acts of Parliament are of little avail so long as the people they are framed to guide do not realize their value or importance, and it is quite certain that the only way to stamp out preventable disease is to educate every member of the community to feel the importance of the laws of health. A great international Congress like this brings the subject prominently before the public and has a valuable influence on the country in which it is held. I have already detained you too long. But I must add, as chairman of the organizing committee, that we have endeavoured to make the Congress useful and agreeable to those who have honoured us with their presence. The success which we have had is mainly due to our secretary-general (Dr. Poore), our foreign secretary (Dr. Corfield), and, as far as India is concerned, to the energy of Mr. Digby. The excellence of the social arrangements is entirely due to the organizing power and tact of the secretary of the reception committee, Mr. Malcolm Morris. But you will have an opportunity of thanking the executive before the end of this meeting. If there have been shortcomings, the organizing committee much regret them. The only apology we can offer is that a voluntary organization suddenly created to fulfil the requirements of the moment may have been somewhat strained at first by the number who appeared on Monday morning—a number far in excess of that which former experience led us to anticipate, and I would say in conclusion, in the words of our poet Prior—

> "Be to our virtues very kind.
> Be to our faults a little blind."

[1] Mariani *Lupercalia*, p. 3°4 of Baehrens, *Frag. poet. Rom.*

Digitized by Google

The meeting next discussed the place of the next Congress; we have already stated that Budapest was fixed upon.

Votes of thanks completed the business. Among these, Dr. Sell (Germany) moved the following resolution:—

"That His Royal Highness the President be respectfully requested to convey to Her Majesty the Queen the dutiful thanks of this Congress for Her Majesty's gracious act in becoming Patron of the Congress, and for the magnificent hospitality shown by Her Majesty to members of the Congress during their sojourn in England."

Prof. Kusý (Austria) seconded the resolution.

Colonel Woodhall (United States) said that all members of the Congress must desire to express their gratitude for the way in which they had been received by that gracious lady Her Majesty the Queen, whose purity and dignity of life had enabled her to extend her empire of love and respect over even American citizens.

The resolution was unanimously agreed to.

His Excellency M. Gennadius, the Minister for Greece, moved the following resolution:—"That the best thanks of the Congress be dutifully tendered to His Royal Highness, the Prince of Wales, the President of the Congress, for the untiring interest which His Royal Highness has manifested in the Congress, and to which the success of the Congress is to be largely attributed."

Finally, the Chairman proposed a vote of thanks to the officers of the Association, whose unsparing work and indefatigable energy had so largely conduced to the success of the undertaking. He coupled with the vote the names of Dr. G. V. Poore, the hon. secretary-general, Prof. W. H. Corfield, the hon. foreign secretary, and Mr. Malcolm Morris, the hon. secretary of the reception committee.

The vote was warmly received, and was unanimously adopted.

The Permanent International Committee have appointed the following International Sub-Committee to prepare a scheme for the organization of future Congresses. The Sub-Committee consists of Prof. Dr. Brouardel, Hon. LL.D. Cantab. (France), Prof. Dr. Fodor, Hon. LL.D. Cantab. (Hungary), and Prof. Corfield (England), to represent Hygiene; and M. Körösi (Hungary) and Dr. Janssens (Belgium) to represent Demography.

It is understood that the Sub-Committee will consider the advisability of forming Permanent Committees in various country, the plan of having Committees outside the country in which the Congress is held having proved so successful in obtaining Foreign Members for the London Congress, at which it was adopted for the first time.

This week we give an account of the work done in the Section of Preventive Medicine.

In this Section the President, Sir Joseph Fayrer, K.C.S.I, F.R.S., commenced the proceedings by delivering the following inaugural address:—

My first duty on occupying this seat is to make fitting acknowledgment of the honour which has been conferred on me, and to assure those to whom I am indebted for it that, as I appreciate the distinction highly, so, with the aid of my colleagues in this Section, and the support of the many eminent men of science who will take part in its work, I hope to discharge faithfully the important trust reposed in me. My next and most agreeable duty is to offer to all who honour us with their presence, or who propose by co-operation to forward the objects of the Congress, a most hearty welcome and cordial recognition of the interest in it manifested by their presence; to express a hope that the deliberations and conclusions which result from their wisdom and experience may advance our knowledge, and tend to enhance the welfare of the human race. This hope is based upon the universal recognition of the need of, and capacity for, improvement in the conditions upon which physical well-being, immunity from disease, and prolongation of life depend; and this is evinced by the assembling together in this Congress of men of science from all parts of the world, who have devoted themselves to the great international, humanitarian purpose of ameliorating the conditions of mankind everywhere, so far at least as the application of the laws of health, and to some extent those of sociology, can affect this consummation. To all, then, we in this great city, who are interested in the progress of hygiene and demography, offer our cordial greeting, and express an earnest desire that our visitors may derive pleasure and benefit from their sojourn in London, and from the proceedings of the great assembly of which they form so important a part.

Before I invite Dr. Cuningham to open the first subject for discussion, it is right that I should make a few preliminary remarks on the general scope and objects of the work comprised in this section. I do not intend to occupy much of the short and valuable time at our disposal by discussing any special subject, or by anticipating that which those who follow me may have to say, but shall confine myself to a brief notice of the present aspects of preventive medicine, its recent development, how much it has operated and is now operating for the public good, how slowly but surely it is dispelling the cloud of ignorance and prejudice which has overshadowed and impeded the progress of sanitation, and how it is gradually imbuing the public mind with the conviction that prevention is better and often easier than cure, that health may be preserved, disease avoided, and life prolonged by the study and observance of certain well-known laws, which, correlating the individual with his surroundings, determine his well-being when conformed to, deteriorate or prevent it when neglected, and should enforce the maxim, "Venienti occurite morbo." Unprecedented progress in human knowledge characterizes the present century, and has not been wanting in preventive medicine. It is, however, during the last half of it that advance has been most remarkable, whilst it is in a later part of that period, that it has so established itself in the popular mind as to have passed from the region of doubt and speculation into that of certainty. It is now pretty generally understood that about one-fourth of all the mortality in England is caused by preventable disease, that the death-rate of large communities may be reduced much below that at which it has been wont to stand, the average duration of life may be made to approximate nearer to the allotted fourscore, and that the conditions of living may be greatly ameliorated. The chief obstacles to improvement have been ignorance and want of belief; a better knowledge of the laws of life and health, a more rational comprehension of the nature and causes of disease, are gradually but surely entailing improvement in the conditions of living and in the value of life, and the diminution and mitigation, if not extinction, of morbid conditions which have in past times proved so injurious or destructive to life. In short, as Dante says:

"Se' l mondo laggiù ponesse mente
Al fondamento che natura pone,
Seguendo lui avria buona la gente."
"Paradiso," viii., 142.

Such are the subjects contemplated in the work of this Section, and as far as time permits the most interesting of them will be discussed. Those selected are of great importance in their relations to public health; let us hope that observers who have formed their opinions from experience in other countries and under different circumstances may throw new light on them.

In the brief space of time at my disposal it would be impossible to give a continuous outline of the progress of preventive medicine during the past, or to trace its growth and development out of ignorance and superstition to its present well-established foundation on a scientific basis. It is of happy augury for mankind that the subject of public health is now fairly grasped by popular sentiment, and that, though ignorance, opposition, and vested interests still contest the ground, progress is sure, and the light of science is illuminating the dark places. It is now better appreciated than it ever has been, that the causes which induce disease and shorten life are greatly under our own control, and that we have it in our power to restrain and diminish them, and to remove that which has been called "the self-imposed curse of dying before the prime of life." It is, indeed, only recently that the resources of medical science have been specially devoted to the prevention as distinguished from the cure of disease, and how far successfully I hope in a few words to show, whilst I trust the proceedings of the various Sections of this Congress

Digitized by Google

will indicate how much remains to be done. Did time permit, I might illustrate the progress of preventive medicine by contrasting the state of England with its population of more than 29,000,000 during the Victorian with the England of the Elizabethan age with its 4,000,000. I might remind you of the frightful epidemics which had devastated the land, in the forms of black death, sweating sickness, plague, petechial typhus, eruptive fevers, small-pox, influenza, and other diseases, such as leprosy, scurvy, malarial fever, dysentery, &c., of the wretched mode of living, bad and insufficient food, filthy dwellings, and ill-built towns and villages, with a country uncultivated and covered with marshes and stagnant water (according to Defoe, one-fifteenth part of England consisted of standing lakes, stagnant water, and moist places, the land unreclaimed, and with the chill damp of marsh fever pervading all). The homes of the people were wooden or mud houses, small and dirty, without drainage or ventilation, the floors of earth covered with straw or rushes, which remained saturated with filth and emitting noxious miasmata. The streets were narrow and unpaved, with no drains but stagnant gutters and open cesspools, while the food was principally salted meat with little or no vegetable. To this may be added a large amount of intemperance and debauchery. As it is, I can only just allude to them. In such conditions disease found a congenial nidus, and by a process of evolution assumed the various epidemic forms which proved so destructive to life. Some of these have gone, let us hope never to return, and the conditions which fostered if they did not cause them have gone also. Can we venture to hope that it will be the same with those that remain? Our immunity during the last diffusion of cholera gives some ground for thinking it may be so, if, indeed, the Legislature and popular intelligence should be of accord on the subject.

If we turn to the present, we find that great improvements have gradually been made in the mode of living; the houses are better constructed, the drainage and ventilation are more complete, the land is better cultivated, and the subsoil better drained; marsh fever and dysentery, at one period so rife, are unknown, and leprosy has long since disappeared. The death-rate is considerably reduced, and the expectancy of life enhanced. Water is purer, food is more varied and nutritious, clothing is better adapted to the climate, the noxious character of many occupations has been mitigated, and the mental, moral, and physical aspects of the people altogether improved; education is general, a better form of government prevails, and the social conditions are far in advance of what they have been; but still the state of our cities shows that improvement is demanded, and one object of this Congress is to point out why and how this may be effected, not only in this country but throughout the world.

If we inquire into the effects of certain well-known diseases, we find that they are less severe in their incidence, if not less frequent in their recurrence. With regard to small-pox, since the passing of the first Vaccination Act in 1840, the death-rate has diminished from 57·2 to 6·5 per 100,000 for 1880–84, though for the five years 1870–74 it was 42·7, thus showing that there was still much to be learnt about vaccination. Enteric fever was not separated from typhus fever before 1869, but since then the death-rate has decreased from 0·39 to 0·17 per 1000, and it has been shown that this improvement was synchronous in different parts of England with the construction of proper drains. The diminution in the death-rate from typhus fever is quite as striking, and this also is shown to have run parallel with improved sanitation in more than one large town. The death-rate from scarlatina fluctuated between 97 and 72 per 100,000 between the years 1851 and 1880, and though it has diminished considerably of late years (17 per 100,000 in 1886), a corresponding increase in the death-rate from diphtheria has taken place; this may be due in part to a better differentiation of the two diseases. In 1858 it was reported that phthisis killed annually more than 50,000 people; the death-rate from this disease has not decreased very much for England and Wales, but it has done so in some large towns, notably in Liverpool; and Dr. Buchanan and Dr. Bowditch of Massachusetts both showed a striking parallelism between the diminution of the death-rate from this cause and the drying of the soil resulting from the construction of sewerage works. Cholera first appeared in England in 1831, and there were epidemics of it in 1848–49, 1853–54, and 1865–66, but the number of deaths diminished each time it appeared, and though it has been present since, it has never reached the height of an epidemic. This is fairly attributable to local sanitary rather than to coercive measures. Preventable disease still kills yearly about 125,000, and, considering the large number of cases for every death, it has been calculated that 78¼ millions of days of labour are lost annually, which means £7,750,000 per annum: this does not include the days lost by the exhaustion so often induced by the still too numerous unhealthy houses of the poor. Towns, villages, and houses are still built in an insanitary way; the death-rate is still higher and the expectancy of life lower than it should be, and though we have got rid of the terrible plagues of the middle ages, yet in this century, now closing, other epidemics have made their appearance: cholera has four times visited us; fevers, eruptive diseases, and diphtheria have prevailed; influenza has appeared several times, even recently, and after leaving us last year, only to return with renewed virulence, caused in the United States a mortality almost equa to that of the plague. Much has been done, and a great deal of it in what is called the pre-sanitary age, but much remains to be effected. Let us hope that the future may be more prolific of improvement than the past; international philanthropy seems to say it shall be so. That we can exterminate zymotic disease altogether is not to be expected, but there cannot be a doubt that we may diminish its incidence, and though we may never be able to reach the "fons et origo mali," yet we can make the soil upon which its seed is sown so inhospitable as to render it sterile. The scope and objects of preventive medicine are not limited to the removing of conditions which give rise to zymotic disease, nor even of those which compromise otherwise the physical welfare of mankind, but should extend as well to a consideration of the best means of controlling or obviating those which, attending the strain and struggle for existence, involve over-competition in various occupations, whether political, professional, or mercantile, by which wealth or fame is acquired or even a bare livelihood is obtained, and under the pressure of which so many succumb, if not from complete mental alienation, from breakdown and exhaustion of the nervous system, which give rise to many forms of neurotic disease and add largely to the numbers of those laid aside and rendered unfitted to take their due share in the natural and inevitable struggle for existence. Or I might point to the recrudescence of those psychical phenomena manifested by the so-called hypnotism or Braidism, morbid conditions arising out of the influence of one mind upon another; this is a subject which demands not only further investigation, but great precaution as to its application, and claims the watchful notice of preventive medicine on account of the dangerous consequences which may ensue from it.

Again, the abuse of alcohol, opium, chloral, and other stimulants and narcotics, and the evil consequences which may result therefrom, is also a subject worthy of consideration, and will, no doubt, receive it in a communication which is to be brought before this Section.

The possible deleterious influence of mistaken notions of education, as evinced in the over-pressure which is exercised upon the young, the predominance of examinations, their increasing multiplication and severity, and the encouragement of the idea that they are the best test of knowledge, whilst true mental culture is in danger of being neglected, and physical training, if not ignored, left so much to individual inclination—this is another subject which demands the jealous scrutiny of preventive medicine, whose duty it is to safeguard the human race from all avoidable causes of either physical or mental disease.

Though preventive medicine in some form has been practised since the days of Moses, yet it has received but little recognition until a comparatively recent period; when science developed and observation extended, medical men and others became impressed with the influence of certain conditions in producing disease, and thus it was forced upon the public conscience that something must be done: and when philanthropists like John Howard devoted life and property to the amelioration of such awful conditions as existed—*e.g.* in our gaols, where the prisoners not only died of putrid fever, the result of ochletic causes, but actually infected the judges before whom they came reeking with the contagion of the prisons—rude sanitary measures gradually came into operation and partially obviated these evil conditions, but it was not before the middle of this century that any scientific progress was made; it was when Chadwick, Parkes, and others initiated the work by which they have earned the lasting gratitude of the

human race that preventive medicine became a distinct branch of medical science. The sanitary condition of towns and communities is not dependent on the views or exertions of individuals alone, for they are and have been for the last fifty years largely cared for by the Legislature, and a variety of Acts have been passed which deal with questions concerning the public health; indeed, were all the provisions enforced, little would remain to be desired on the part of the executive Government, but as many of them are permissive, not compulsory, the benefit is less complete than it might be. The old difficulty of prejudice combined with ignorance still too often stands in the way, and, despite evidence which on any other subject would be conclusive, the most obvious sanitary requirements are often ignored or neglected. Many thousands of lives have been saved by the Sanitary Acts now in force; but there is little doubt that more thorough organization under State control, as under a Minister of Public Health, would have most beneficial results, and would save a great many more. We must acknowledge, however, that we are much indebted to the action of the Local Government Board, under whose able administration the most crying evils are gradually being rectified. Through the wise precautions enacted by it against the importation and diffusion of epidemic disease, when other parts of Europe were affected by cholera, this country escaped, or so nearly so as to suggest that it was to sanitary measures we owed our immunity. That there is something in the nature of epidemics which brings them under the dominion of a common law as to their extension seems certain; that there is much about them we do not yet grasp is equally true, but it is as surely the case that local sanitation is the preventive remedy as it is that coercive measures to arrest their progress are unavailing.

Under the improved system of sanitary administration which now obtains, and is gradually developing to a greater state of perfection, the sanitary administration of every district in the country is intrusted to the care of duly qualified health officers—a system from which excellent results have already accrued, and from which better still may be anticipated. The records of the past fifty years prove the influence exerted by sanitary measures on vital statistics. The first reliable tables from which the expectancy of life may be derived show that in 1838 to 1854 it was for males 39·91 years, for females 41·85 years; by the tables of 1871 to 1880 it had increased to 41·35 for males and 44·66 for females. It is shown also that the expectation of life increases every year up to the fourth year, and decreases after that age. For males up to nineteen years it is higher by the last tables, but after that age it is higher by the old table; for females it is greater by the new table up to forty-five, but after that age it is less. The improved sanitation saves more children's lives, but the conditions of gaining a living are harder than they were at the time of the first table, which accounts for the expectancy of life for adult men being less. Women remain more at home, where the better sanitation tells, and are not subject to quite the same conditions as men, so that their expectancy of life is greater than by the old tables up to the age of forty-five. A further proof of the effects of sanitary work is a decreased death-rate. Let us compare the death-rates of England during past times with the present; whether they be equally significant for other countries I cannot say, but these, at all events, sufficiently prove the point in question:—

DEATH-RATE.

1660–79	... 80	per 1000	1870–75	... 20·9	per 1000
1681–90	... 42·1	,,	1875–80	... 20·0	,,
1746–55	... 35·5	,,	1880–85	... 19·3	,,
1846–55	... 24·9	,,	1885–88	... 18·7	,,
1866–70	... 22·4	,,	1889	... 17·85	,,

In some parts of England, where the main object is the recovery or maintenance of health, the death-rate is down to 9 per 1000, while in others, where the main object is manufacture and money-making, it is as high as 30 per 1000. Nowhere, I think, have the beneficial results of sanitary work been better illustrated than in India during the past thirty years. A Royal Commission was appointed after the Crimean war to inquire into the sanitary condition of the British Army, and this in 1859 was extended to India. The European army was the special subject of it, but the native troops were referred to incidentally. Here the inquiry had to deal with a large body of men, concerning whom, their conditions of existence being well known, reliable information was accessible. It was ascertained that up to that time the annual death-rate over a long period had stood at 69 per 1000. The inquiry resulted in certain changes and improvements in the housing, clothing, food, and occupation of the soldier. Since those have been carried out there has been a steady decline in the death-rate, and the annual reports of the Sanitary Commissioners to the Government of India give the rates as: in 1886, 15·18 per 1000; 1887, 14·20 per 1000; 1888, 14·84 per 1000. During some years it has been even lower, down to 10 per 1000, whilst the general efficiency of the troops has increased. It is not easy to estimate the money equivalent of this, but if we take the rough standard which values each soldier at £100, a simple calculation will show how great is the gain, and who can estimate the value of lives saved and suffering avoided? As to native soldiers with whom the European troops may be compared, I find that the death-rate was: in 1886, 13·27 per 1000; 1887, 11·68 per 1000; 1888, 12·84 per 1000. Famine, cholera, and other epidemic visitations in some years disturb the regularity of the death-rate; under less favourable conditions of living, as in the case of prisoners in the gaols, it is somewhat higher. In the Indian gaols, for example, it was: in 1886, 31·85 per 1000; 1887, 34·15 per 1000; 1888, 35·57 per 1000.

On the whole, all this indicates improvement,[1] and as regards the civil population progress also is being made; but here, from so many disturbing causes, the figures are neither so easily obtained nor so reliable. The comparatively large mortality is due to neglect of the common sanitary laws added to extremes of climate, which favour the incidence and diffusion of epidemic disease, and intensify it when it has once appeared. A Sanitary Department has existed in India since 1866, and every effort is made by Government, at no small cost, to give effect to sanitary laws; there can be little doubt that the results, so far, are good, that disease generally is diminishing, and that life is of longer duration. An important result of the observations of the able medical officers of the Sanitary Service of India has been to show that cholera is to be prevented or diminished by sanitary proceedings alone, and that all coercive measures of quarantine or forcible isolation are futile and hurtful. Here I may say that, large as may appear the death-rate from cholera in India (*i.e.* in 1888, 1·99 per 1000 for the European army and 1·35 for the civil population), it is small compared with that of fevers, which caused in 1889 4·48 per 1000 in the European army and 17·09 in the civil population; but there is every reason to believe that these also are becoming less fatal under the influence of sanitary measures. In preventive as in curative medicine, knowledge of causation is essential. It is obvious that any rational system of proceeding must have this for its basis. A certain empirical knowledge may be useful as a guide, but no real advance can be expected without the exactitude which results from careful scientific observation and induction; the spirit of experimental research, however, is now dominant, and progress is inevitable. How much we owe to it is already well known, whilst under its guidance the reproach of uncertainty which attaches to medicine as a science is disappearing. Recent advances in physiology, chemistry, histology, and pharmacology, have done much to throw light on the nature and causes of, and also on the means of preventing or of dealing with, disease. It is impossible to exaggerate the value of the scientific researches which have led to antiseptic methods of preventing the morbific action of micro-organic life, whether the toxic effects produced by them, or those induced autogenetically in the individual. Theory has here been closely followed by its practical application in prevention and treatment of disease, whilst the study of bacteriology, which is of such remarkable pre-eminence at the present time, is opening out sources from which may flow results of incalculable importance in their bearing on life and health. That the conclusions arrived at are always to be depended on I doubt, and it seems that scientific zeal may perhaps sometimes outrun discretion. That it might be wiser to postpone generalization has, I think, been more than once apparent, whilst the expediency of further investigation before arriving at conclusions which may subsequently prove to be erroneous should not be lost sight of; but it has probably

[1] "It is to be noticed with regret that during the last five years there has been a tendency to revert to a higher death-rate and percentage of sickness. Let us hope this will prove only transitory; the attention of sanitary authorities both at home and in India is anxiously directed towards the removal of whatever may be the cause of it. It is shown both by the vital statistics and the history of the chief diseases that there is in India an enormous amount of preventable sickness and death," but "that the local insanitary conditions or local disease causes are well known and widespread."—A. S. C.'s Reports for 1889.

Digitized by Google

ever been so in the course of scientific progress, that in the enthusiasm of research, which is rewarded by such brilliant results, early generalization has too often been followed by disappointment, and it may be by temporary discouragement of hopes which seemed so promising.

It would be well to bear in mind a caution recently given by the Duke of Argyll, "that we should be awake to the retarding effect of a superstitious dependence on the authority of great men, and to the constant liability of even the greatest observers to found fallacious generalizations on a few selected facts" (*Nineteenth Century*, April 1891). Still, it is in the region of scientific research by experiment that we look for real progress, and we can only deplore the mistaken sentiment, the false estimate, and the misconstruction of its aspirations and purposes, which have placed an embargo on experiment on living animals, rendering the pursuit of knowledge in this direction well nigh impossible, if not criminal; whilst for any other purpose, whether of food, clothing, ornament, or sport, a thousandfold the pain may be inflicted without question. The inconsistency of the sentiment which finds unwarrantable suffering in an operation performed on a rabbit, when the object is to preserve human or animal life or prevent suffering, but which raises no objection to the same animal being slowly tortured to death in a trap, or hunted or worried by a dog, needs no comment; whilst the spirit which withholds from the man of science what it readily concedes to the hunter is, to say the least, as much to be regretted as it is to be deprecated.

It must be remembered that, important as are the researches into microbiology, there are other factors to reckon with before we can hope to gain a knowledge of the ultimate causation of disease. It is not by any one path, however closely or carefully it may be followed, that we shall arrive at a full comprehension of all that is concerned in its etiology and prevention, for there are many conditions, dynamical and material, around and within us which have to be considered in their mutual relations and bearings before we can hope to do so; still, I believe we may feel satisfied that the causes of disease are now being more thoroughly sought out than they ever have been—all honour to those who are prosecuting the research so vigorously—and that though individual predilection may seem sometimes to dwell too exclusively on specific objects, yet the tendency is to investigate everything that bears upon the subject, and to emphasize all that is implied in the aphorism, *Salus populi, suprema lex.*

The morning sitting of the Section and most of the afternoon sitting was devoted to papers and a discussion on "The Mode of preventing the Spread of Epidemic Disease from one Country to another."

The chair was occupied successively by the President, Professeur Brouardel of Paris, and Prof. da Silva Amado of Lisbon.

Surgeon-General Cuningham, of London, opened the discussion, and said the modes of prevention of spread of disease from one country to another were three in number, (1) quarantine, (2) medical inspection, (3) sanitary improvements. In his remarks he dealt chiefly with cholera, and he held that the chief factor of cholera, being carried by atmospheric currents, cannot be excluded from any country, and where it has been distributed over any area it excites the disease directly in many persons who are predisposed to it, and forms foci of it whenever it finds localities suitable for its increase; these are often very limited in extent, not embracing more than a single house, or even a portion of a house, or ship; the mortality among the steerage passengers in the latter is often very great, while the cabin passengers and all the crew have scarcely a case. Such foci are always badly ventilated, and the emanations arising in them acquire much greater density than in the open air; as a natural consequence the clothing of those who reside in them absorbs an amount of the emanation sufficient to produce cholera in susceptible persons outside until it has been dissipated by exposure; those so affected, however, and the others who have contracted the complaint apart from such foci, do not seem to have any such influence, it being not the body but the emanations from the locality which generate the disease. Cholera, therefore, cannot be excluded from any country by general quarantine. All that can be done is by hygienic measures to improve the health of the population, and to remove the conditions which favour the formation of foci. The placing ships which arrive with cholera on board under observation, removing their crews and passengers to suitable localities on shore until the disease ceases among them, are very proper precautions, and may prevent a small amount of the disease among the surrounding population, but can never prevent an epidemic if the necessary factors be in progress.

Inspector-General Lawson then followed with a paper on "The Communicability of Cholera from one Country to another."

To draw up a plan to prevent the extension of a disease, say cholera, from one country to another, with any prospect of success, it is necessary to have a general acquaintance at least with the different factors which contribute to the result, and of their mode of operation. The existing information on these points falls far short of these requirements, and its increase has been enormously impeded by the belief that man himself is the chief agent in diffusing the disease; and by interpreting the evidence obtained from various sources with an undue bias in favour of the theory. There has been, in short, and still remains, a most serious error in assuming that personal communication is the principal factor; and a no less extensive error in the methods and reasoning by which the central idea of diffusion by man was advocated.

The character and causes of cholera must be derived from a critical examination of all the evidence Nature presents, and from a study of the methods she herself adopts, instead of from our *a priori* deductions. Cholera occurs in two different forms: simple cholera or cholera nostras, of little severity, and attributed to local causes; and Asiatic epidemic, or malignant cholera, always a serious disease, and by many attributed to a poison given off by those labouring under it to others, and so diffused until it becomes epidemic.

Since 1832, when cholera visited Europe in the epidemic form, cholera nostras has been observed to fluctuate every few years, and with the milder cases occur a certain number presenting all the characters of the malignant disease; these cases occur singly or in small groups, but in every instance they accompany epidemics of varying severity, at no very great distance off, and are under the same "epidemic influence."

Those who support the theory that man diffuses cholera are, necessarily, required to show that persons under the disease must arrive at points where it has not yet appeared, before it commences in these latter, and that the first attacks in the new locality have been in persons exposed to the imported cases: but there are now a good many instances of epidemics springing up in localities at a distance from where the disease was already prevailing, and without any trace of importation, and where those first attacked had resided in the country for many months in succession without communication with any previous case. Such were the outbreaks at Southampton in 1865, at New Orleans in 1873, and at Toulon and the south of France in 1884, all of which were most carefully investigated on the spot. The only other conclusion open was that the necessary factors were supplied by epidemic influence; and if supplied in one instance, supplied in all: where there appeared to have been importation at the commencement of the outbreak, it must not be assumed that the disease was communicated by man unless the epidemic influence could be excluded, as at present it could not. It seemed probable that the exciting factors were conveyed by the air, whether fully or only partially developed, and consequently it was not in our power to exclude them; but much might be done by hygienic and other local means to limit their development in the localities they reached, and so to avoid excessive mortality.

Dr. Ashburton Thompson, official delegate of the Government of New South Wales, followed with a paper entitled "Quarantine in Australasia: Theory and Practice." He said that the amount of traffic which had to be dealt with was an important consideration in all questions of practical quarantine. The Australasian Sanitary Conference of Sydney, N.S.W., 1884, was attended by delegates of each of the six Governments, and by the speaker. Their resolutions were unanimous, accepted by each Government, and presented to each Parliament. They had not been modified since 1884, and were therefore those received in Australasia at the present day. Limited quarantine, medical inspection, the outcome of England's local conditions, was exactly suited to them, but not necessarily suitable, therefore, where local conditions differed from England's. The *first* proposition of the Conference was that *the degree of protection which quarantine measures can afford varies inversely with the ease of communication between the infected country and the country to be defended.* The difference between English and

Digitized by Google

Australasian conditions was described. The Conference rejected ancient quarantine as a principle of action, and on account of easy and daily interchange of population between the six territories decided to regard Australasia as constituting one epidemiological tract, and consequently to relinquish all quarantine as against each other. Then, before adopting resolutions which would affect others, they put themselves in order by declaring in a *second* proposition that *quarantine can yield protection commensurate with its costs only to countries whose internal sanitation is good;* and they recognized defects inherent in all quarantine measures by declaring, in a *third* proposition, that *the function of quarantine is not to exclude infection, but to lessen the entering number of foci of infection*, and thus made it clear that exclusive reliance was not placed by them on quarantine as a defence against imported disease. Having thus indicated what should be refrained from, it proceeded to say what should be done. *Nations whose internal sanitary organization was not perfect cannot afford to refer the observation of suspects to the country at large.* It was decided consequently that limited quarantine should be employed against ships actually carrying cases of exotic disease—that was, that vessels and equipment should be cleansed forthwith and held for delivery to owners at earliest possible date, but that the ship's company should be detained in isolation for periods slightly in excess of recognized clinical incubation periods. Medical inspection was thus rejected as a principle of action not less than ancient quarantine, but still not inconsiderately; when imported disease was one already familiar ashore, the circumstances were seen to resemble England's, and then medical inspection must (not might or could) be used. Accordingly, in case of scarlatina or the like, patients were removed to ordinary isolation hospital (not quarantine), the quarters cleansed, and the ship discharged in the usual way after five or six hours' detention. These principles were strictly adhered to by the Government of New South Wales since 1884. If not quite so closely by the other five Governments, the reason was probably political rather than commercial or scientific.

Dr. Rochard, of Paris (whose communication was read by Dr. Jules Bergeron), said that the means of preventing the transmission of epidemic diseases, such as the plague, yellow fever, and cholera, were threefold—namely, isolation, disinfection—and sanitation. The first was the simplest and the most radical. It was also the most difficult to use, because it required the intervention of public enactments, and the existence of an *entente internationale*. It was the system of quarantine and of the sanitary cordons. The second was more modern, and was the result of the development of contemporary science. The third rested on the progress of urban hygiene. It was probable that when we had sanitary towns we could brave epidemics. England had spent five millions since the commencement of the century, and it did not fear cholera during the last epidemic. Some of England's resistance to the cholera must be ascribed to its great distance from the source of cholera. M. Rochard next proceeded to detail the means taken at the frontier by the French authorities during the last cholera epidemic in Spain, and expressed the belief that it was necessary to persevere in the employment of those measures which responded to the necessities of the moment and to our present knowledge, until the future developed some better remedy.

Dr. Stékoulis, of Constantinople, after mentioning the methods quarantine and inspection, detailed by previous speakers, said that Turkey was like numerous other countries, one in which sanitary organization had yet to be carried out. If cholera has entered Turkey in these last years by Basjorah (Persian Gulf) and by Camaran (Red Sea) it was that the lazarets are not in accord with the progress of sanitary science. The pilgrimage of the Mussulmans to Mecca is also a great source of danger to the country. The lazarets of Turkey ought to be made sanitary, and there would be a great danger removed.

Dr. Hewitt, of Minnesota, U.S.A., said they had very little to do in his State with disease properly called epidemic except that of small-pox. Cholera had but once obtained something of a lodgment, and then it came directly from the port of New York. Small-pox came to them directly through emigration from the ports of England, and most of it came through the Gulf of St. Lawrence. Only the other day cases came from Liverpool to Minnesota. He mentioned one case in which infection was carried in the clothing of a woman who did not have the disease herself, but had been exposed on shipboard to it. The epidemic resulted in 300 deaths. For interior States like Minnesota the demand was that there should be complete sanitary central organization, with local organization in direct relation thereto, and that this organization should stand in direct relation to the quarantine service, which should be bound to give notice to the interior authorities of the presence of disease or infection, and that they should all co-operate for its control.

Dr. Simpson, of Calcutta, stated that the real source of cholera epidemics in Europe was, in his opinion, from emigrants and pilgrims coming over land and in ships to Mecca, where there was a focus 2000 miles nearer Europe than any Indian port.

Dr. Leduc, of Nantes, agreed with Dr. Cuningham as to the need of improved sanitary conditions in our towns, but he strongly disagreed with him when he proposed the suppression of quarantine. Modern science teaches us that contagious diseases are spread by wandering germs: isolation must therefore be a preventive to the spread of the disease, and quarantine presents us with the best means of isolation, so that to propose the suppression of quarantine was to propose a measure at once irrational and contrary to the principles of modern science.

Dr. Thorne Thorne, of London, spoke of the need of sanitary reform in towns, and deprecated the so-called protection of a country by means of cordons, quarantine, &c. The sixteen days' quarantine decided at Constantinople in 1866 failed, the ten days' quarantine decided at Vienna failed, and yet the five days' suggested at Rome is to succeed. The contention is altogether illogical.

Prof. Stokvis, of Amsterdam, said that at the International Medical Congress at Amsterdam there was a discussion on quarantine, in which the same arguments for and against were used as now. He then had no steadfast conviction. Now he had, and it was, that the only way to prevent the spread of epidemic diseases, and especially of cholera, was to make sanitary improvements. He had arrived at this conclusion by the study of the history of cholera in India, where cholera diminishes as sanitation improves. In the Dutch Indian Archipelago, where quarantine is of no consequence, the following figures show the great diminution in the death-rate which ensued on sanitary improvement. From 1864–78 the death-rate in the European army was 15 per 1000. In 1878 artesian wells, &c., were made. In 1879–83 the death-rate fell to 6·4 per 1000; and in 1884–88 to 3·5 per 1000. These figures are very striking, and lead one to hope that the saying of the late Prof. De Chaumont will come true, that the time will arrive when cholera will only be an historical curiosity.

The following gentlemen also took part in the discussion: Dr. Felkin of Edinburgh, Prof. Brouardel of Paris, Sir Joseph Fayrer, Surgeon Major Pringle, Surgeon-General Cook, Dr. Robert Grieve of British Guiana, Dr. Ruijsch of the Hague, Brigade-Surgeon Staples, Surgeon-Generals Cayley, Ewart, and Beatson, Señor Vicente Cabello, and Brigade-Surgeon McGann.

In the afternoon, Sir John Banks, K.C.B., in the chair, Dr. Manson read an elaborate paper on "The Geographical Distribution, Pathological Relations, and Life-history of *Filaria sanguinis hominis diurna* and *Filaria sanguinis hominis perstans* in connection with Preventive Medicine." The paper was illustrated by numerous microscopical specimens.

Dr. Manson said that the discovery of the blood-worms herein named *Filaria sanguinis hominis diurna* and *Filaria sanguinis hominis perstans* suggests an investigation into their possible pathological relations, and into their life-histories, with the view to intervention in respect to them of preventive medicine.

The facts that these parasites and the disease known as negro lethargy, or sleeping sickness of the Congo, are endemic in the same region, the West Coast of Africa; that neither can be acquired unless in this particular region; and that sleeping sickness may declare itself many years after the endemic region has been quitted, and that these filariæ continue to live for many years after the negro has left Africa; suggest a possible relationship between these parasites and this disease.

A papulo-vesicular skin disease called craw-craw is endemic in the sleeping sickness region, and sleeping sickness is often accompanied by a similar papulo-vesicular skin disease, probably the same. O'Neil found a filaria-like parasite in the vesicles of craw-craw. Nielly considers a disease he calls *dermatose parasitaire*, which he found in a lad in France, the same as the African craw-craw; he discovered in the vesicles of the skin in this case the same or a similar parasite to O'Neil's. Nielly, at the same time, found an embryo filaria in his patient's blood which was undoubtedly an earlier form of the skin worm. From

Digitized by Google

this the inference may be drawn that, in certain cases, at all events, of sleeping sickness a filaria embryo is present in the blood.

Filaria s. h. diurna and *Filaria s. h. perstans* have both been found in a case of sleeping sickness.

These facts taken together amount to a presumptive case against one or other of these parasites as the cause of sleeping sickness.

The probable life-histories of these worms is then indicated, the *Filaria loa* being considered the parental form, and an insect, called the mangrove fly, the intermediary host of *Filaria s. h. diurna*. The parental form of *Filaria s. h. perstans* is not known, but, assuming that the worm of craw-craw, sleeping sickness, and *dermatose parasitaire* is the same, and that the skin form is an advanced stage of the embryo filaria found in the blood, then, arguing from the analogy to what happens in the case of the embryo of *Filaria medinensis*, which closely resembles this skin parasite, the probable intermediary host of *Filaria s. h. perstans* is a freshwater animal, possibly a cyclops.

Provided the hypotheses as regards these parasites and the diseases they produce are correct, both disease and parasites may be avoided by securing a pure water supply to which the intermediary hosts of the parasites do not get access.

Travellers, missionaries, and others in Africa are appealed to for assistance in clearing up the subject, and for further information.

An appendix to the paper contains directions for demonstrating in the surest, most rapid, and most effective way the presence or absence of filaria embryos in blood, and of making collections of slides of blood for storage and future examination.

Dr. Sonsino, of Pisa, made a few remarks on Dr. Manson's paper. The meeting then adjourned.

On Wednesday, August 12, the chair was occupied successively by Sir Joseph Fayrer, Dr. Pistor of Berlin, and Surgeon-General Roth of the Saxon Army.

Discussion on Diphtheria.

Dr. Edward Seaton, of London, opened a discussion on "Diphtheria, with special reference to its distribution and to the need for comprehensive and systematic inquiry into the causes of its prevalence in certain countries and parts of countries, with a view to its prevention."

Dr. Seaton said that he should confine himself in introducing this subject to leading statements, showing the necessity for comprehensive and systematic inquiry to be promoted by Government into the causes of the prevalence of diphtheria in certain countries and parts of countries, with a view to its prevention. He first of all pointed to the special prevalence of the disease, as shown by Dr. Longstaff, in Norfolk and Wales, and the comparative freedom of Devonshire, Cornwall, and the Midlands. He then dwelt on the facts that the disease prevailed more in rural than urban districts, although it has shown of late years an increasing preference for urban populations, especially that of London. He showed the independence of the disease of what are ordinarily called sanitary conditions, and illustrated this by a table taken from Dr. Thorne Thorne's recent lectures at the Royal College of Physicians, showing the fall in enteric fever mortality in England and Wales which had synchronized with a rise in the mortality from diphtheria. He further illustrated the independence of diphtheria prevalence of what are usually termed sanitary conditions by experiences gathered from a large manufacturing town in the Midlands, and from certain parts of the metropolis in which he had special opportunities for observation as a medical officer of health, as well as in connection with the work of the Metropolitan Asylums Board, into whose hospitals cases of diphtheria had been received during the last three years. He also gave a recent experience of a Surrey village, in which the disease had prevailed in an epidemic form, shortly after the replacement of the old insanitary cesspool system by a new and elaborately constructed sewerage system. The occurrence of the disease under these circumstances gave rise to the suspicion that there might be a connection between diphtheria and conditions of soil, which needed to be investigated in a comprehensive and systematic manner. In conclusion, he pointed out the importance of these main considerations, viz.: (1) the prevalence of the disease in strikingly different degree in countries in the same latitude and with similar climatic conditions and also in parts of countries close to each other, (2) the fact that it has not apparently been influenced favourably by the adoption of sanitary measures which have been generally found effective in reducing the death-rate, prove the necessity for a comprehensive inquiry by our own Government as well as those of other countries, into the causes which determine the prevalence of diphtheria. Such an inquiry should take into account what has already been ascertained with regard to the occasional causation and spread of the disease by milk, and the influence which schools have on its production and spread, and also the subsidiary influence of dampness, dirt, overcrowding, &c.; but its main object would be to ascertain the local conditions and circumstances which account for the growth of the disease. To ascertain these the inquiries must, of course, be made in countries marked by freedom from the disease as well as in those which suffer from it specially.

Dr. Schrevens, of Tournai, followed with a paper entitled "Contribution à l'étude des causes favorisant les endemies diphthéritiques," of which the following is an abstract.

By investigating carefully how the ravages committed by diphtheria are distributed over the different districts, one can attain more easily to a precise knowledge of the external conditions which favour the harbouring of diphtheritic germs, and which result in such germs being brought into a locality. Investigations were made by the author in Belgium with this object. Thanks to the figures kindly furnished by Dr. Kuborn, the distribution of diphtheria throughout the different provinces of Belgium for the ten years from 1871 to 1880 has been determined. The same having been done for typhoid fever, it was noticed that where this latter disease committed the greatest ravages the same fact was observable in the case of diphtheria; and that where diphtheria secured its smallest number of victims the number of deaths caused by typhoid fever diminished equally. This parallel rise and fall of the mortality caused by typhoid fever and diphtheria is shown in two diagrams placed near each other on the same sheet; in the first, the parallelism is less evident, because one province, East Flanders, forms an exception to the rule I have just laid down; in the second diagram this province is omitted, and the parallel march of diphtheria and typhoid fever stands out clearly. On what does this relation, this agreement rest? On this fact, that these two diseases must be considered as fœcal diseases, as B. Russell, of Glasgow, has remarked. The bacilli of Löffler, like the bacilli of Eberth, develop admirably, prosper, and extend wherever filth and rubbish of all kinds are stored up or spread out; there exists, however, this slight difference between the conditions which are severally favourable to them: impurities on the *surface* of the soil suit the bacilli of Löffler in a special degree, while impurities of the *subsoil* please the bacilli of Eberth better.

Even the exception formed by East Flanders tends to confirm this rule, inasmuch as it is perfectly clear that its surface ought to be more easily cleared of all impurities by reason of the numerous watercourses which furrow it. A further proof that it is, in a special degree, impurities of the surface which serve to harbour diphtheritic germs in certain localities, is the exaggeration of mortality from diphtheria in country districts compared to what obtains in towns; density of the population is not of the least influence on the increase of the mortality due to diphtheria; but the surface of the soil is much better protected in towns against impurities of all kinds.

Another circumstance which may foster diphtheria in a locality is the breeding of certain species of animals presenting a great receptivity for diphtherogenic germs: for example, Italian fowls and game-cocks. The transmission of diphtheria to man by these animals is so well established by the observations collected by the author for several years past that he feels persuaded of the need of further attention being paid to this subject. Finally, a third condition which necessarily fosters diphtheria in a locality is the negligence exercised in the application of measures of disinfection and isolation.

Every case of diphtheria must be notified to the local authority, who will see to it immediately that all the children of the sick person's family be kept away from school as long as any danger of contagion exists. In every case disinfection must be rigorously attended to and performed by special agents. Notification and disinfection ought to be obligatory.

The altitude of the locality does not probably exercise any very great influence. One would suppose that diphtheria would be specially prevalent in low, damp places. Recent observations by the author on the progress of diphtheria in three contiguous parishes of the district of Ath (Œudeghien, Ostiches, and Mainvault), show that in each of these parishes there was a

Digitized by Google

principal seat of the malady, and that in the three parishes this seat was in precisely the most elevated hamlet of all, a fact which from the first appears somewhat strange. One may, perhaps, conclude that Löffler's bacillus does not like too much damp, and that it is in this respect that its character differs from the bacillus of Eberth.

Dr. Hewitt, Secretary and Executive Officer of the State Board of Health of Minnesota, U.S.A., said that his experience covered eighteen years of sanitary service with the disease in an interior State of the American Union with a very complete public health service, consisting of 1575 local boards of health, with a State Board. Notification of infectious disease by physicians, householders, hotel and inn keepers, has been obligatory since 1883 with penalty, as is also isolation and disinfection by the local boards of health. The facts believed to be proven in Minnesota were that the disease is very infectious, that it is communicable by persons and things, that the infection lives and grows outside the body and below the body temperature, that it is very tenacious of life as against measures of disinfection, and lives for long periods in clothing and bedding and on floors and walls. Isolation and systematic disinfection, with the most perfect sanitary regulation, are most efficient at present in the control of the disease. Since these had been in efficient use the prevalence had assumed a family character, limiting itself to one or more associated families, and rarely going beyond, except by evasion of the law on the part of an infected person. What was needed now was more careful collection of the facts of each outbreak with a view to a more accurate knowledge of the disease, not neglecting the preventive and controlling measures now found to be most efficient, as above.

Dr. Jules Bergeron, of Paris, followed with a paper entitled "Note sur la Prophylaxie de la Diphthérie." Dr. Bergeron said that the measures to be taken against diphtheria were disinfection and isolation: disinfection of all clothing, &c, contaminated with secretions from the affected parts; isolation of all cases and of all doubtful cases, such as those of a herpetic character, which are difficult to distinguish from diphtheria in the early stage of the disease. An important question to be answered is, How long ought isolation to continue; how long, in fact, does contagion last? Dr. Bergeron says that he adopts six weeks' isolation as the maximum, and that he has never observed a case of transmission of the disease when a case has been isolated for this period.

Dr. Gibert, of Havre, spoke of diphtheria in Havre. He said that diphtheria appeared in Havre about 1860, and was limited to the Graville Quartier. In 1864, there was an epidemic close to Eryonville. From this date the number of deaths constantly increased, and the disease, which at first was confined to only a few localities, spread throughout the town. The severity of the disease increased until 1885, when a *brigade de salubrité* was formed as an annexe to the Bureau d'Hygiène. The dwellings occupied by diphtheritic patients having been regularly disinfected, the mortality curve has since decreased to such an extent as to justify the hope of its total extinction, provided all the medical men of the town furnish accurate information to the Bureau d'Hygiène.

Dr. S. W. Abbott, of Boston, U.S.A., read a paper on "Diphtheria in Massachusetts from 1871–88." From his observations he concludes that diphtheria is an eminently contagious disease, that it is infectious, not only by direct exposure of the sick to the well, but also through indirect media, such as clothing and other articles that have come in contact with the sick; that the infection is not so great as in the case of some of the other infectious diseases, notably small-pox and scarlet fever. Dr. Abbott also concludes that overcrowding, &c., favours the spread of the disease; but that its transmission through the water supply is not proved. Its transmission is favoured by soil-moisture and damp houses; and the poison may remain infective in houses for a long period.

Mr. Matthew A. Adams, of Maidstone, read a paper on "The Relationship between the Occurrence of Diphtheria and the Movement of the Subsoil Water." The conclusions he arrived at were that the organism of diphtheria inhabits organically polluted surface-soil, and that, subject to suitable conditions of environment, especially as respects moisture, temperature, and food, it thrives and multiplies in the soil, the micro-organism thus produced being liable to displacement from the interstices of the polluted surface-soil, and to dispersal into the superincumbent air; in this manner determining outbreaks of the disease. So that, given the existence of the pathogenic organism, two sets of factors at least are engaged in the production of a state of affairs that culminate in an outbreak of diphtheria. First, those that promote and support the growth of the germ in the soil, such, for instance, as moisture, temperature, air, food, and so on. Secondly, agents of dispersal, by which the germs already existing in the soil are driven out and distributed into the atmosphere, and so come to be breathed by man and animals; for example, sudden rainfall, rise of subsoil water, lowering of barometric pressure.

Mr. Charles E. Paget, of Salford, followed with a paper on "A Local Examination of the Difference in Susceptibility between Old and New Residents."

The general conclusion at which he arrived as the result of an examination of the statistics of Salford was, that a shorter average period of residence before an attack of diphtheria was observed where the general mortality rate was highest and *vice versâ*; that, in fact, the relative incidence of diphtheria during an epidemic period, in respect of length of residence, was dependent to no small extent on general sanitary circumstances.

Prof. D'Espine, of Geneva, followed in the discussion. He drew attention to the great value in the prophylaxis of diphtheria in the systematic washing out of the mouth and pharynx by antiseptic solutions, corrosive sublimate (1 in 10,000), salicylic acid (1 in 2000), and lime-juice. In his practice he used salicylic acid in the strength of 1½ to 2 per 1000.

Dr. Tripe, of Hackney, who followed, said he had had large experience of this disease, as he had been 35 years Medical Officer of Health in Hackney. During that time all deaths had been investigated, and lately all cases, with the result that there was no evidence that insanitary conditions of houses caused the disease, although they might predispose to it. He believed that closing playgrounds in schools is as effectual in checking the disease as closing the schools; that prompt removal to hospital and disinfection of clothing and rooms, burning of infected rags, &c., are the best methods for checking the disease.

Dr. Thursfield, of Shrewsbury, agreed with Dr. Hewitt that dampness had a great deal to do with the etiology of diphtheria; he had himself stated so thirteen years ago in a series of papers on the subject. He thought Dr. Adams's conclusion regarding the connection of the rise and fall of the subsoil water with outbreaks of diphtheria a somewhat hasty generalization.

Dr. Günther of Dresden, Dr. Janssens of Brussels, Dr. Hubert of Louvain, Dr. Escherich of Graz, Dr. Jules Felix of Brussels, and Dr. P. Sonsino of Pisa, also took part in the discussion; many of the speakers emphasizing the need of local antiseptic measures in the prophylaxis of diphtheria.

At the end of the discussion, the following recommendation was unanimously adopted by the Section:—

"That this Section urges the European Governments to make a comprehensive and systemative inquiry into the causes of diphtheria."

On Tuesday afternoon, Sir John Banks, K.C.B., and Overlaege Bentzen, Christiania, occupied the chair.

Discussion of the Preventability of Phthisis.

Dr. Arthur Ransome, F.R.S., read a paper "On the Need of Special Measures for the Prevention of Consumption." He said, that consumption is both curable and preventable will be acknowledged at once by all medical men who have had any experience of modern methods of dealing with the disease.

Its curability is attested (1) by the reports of many pathologists as to the presence of evidence of healed phthisis in a large proportion of bodies examined in public institutions. Many thousands of such examinations have now been made, and the results show that from 25 to 50 per cent. of persons dying from other diseases than phthisis give signs of spontaneous cure of tubercular disease. (2) The testimony of all the most eminent modern physicians is to the same effect, that consumption is distinctly curable.

With regard to the preventability of the disease we have also a strong basis for our faith.

(1) In the marvellous results that followed the improved drainage and ventilation of the barracks of the British army in all parts of the world. Before the year 1854, the mortality from lung disease amongst the picked population of these dwellings was a scandal to the nation, and was enormously greater than that of the ordinary inhabitants of our towns, especially in the battalions sent to warm climates, such as those of India, Ceylon, the West Indies, the Mediterranean, &c.

Digitized by Google

Thanks to the above-mentioned measures, it now stands at from one-third to one-tenth of its former rates.

(2) The influence of improved drainage has been shown by Dr. Buchanan, in his table of towns, contrasting the mortality by phthisis and other diseases before and after the introduction of improvements in this direction; and lastly, by the reduction of the general phthisis rate of the country from 2500 per 1,000,000 in 1867, to 1500 per 1,000,000 in 1889.

My own observation in Manchester and Salford, and those of Dr. Irwin in Oldham, and of Dr. Flick in Philadelphia, point to the existence in towns of tubercular areas and infected houses.

Under these circumstances it seems to me that the duty of sanitary authorities is clear. They should regard phthisis as a disease to be dealt with on precisely the same lines as the analogous diseases, typhoid fever, cholera, and leprosy—diseases, namely, which are slightly, if at all, directly contagious, but which spread by material thrown off from the bodies of the patients. The means to be employed to this end would also be very similar: (1) notification of cases; (2) disinfection; (3) hospital accommodation; and (4) general sanitary measures, such as ventilation, drainage, and reconstruction of unhealthy areas.

(1) *Notification.*—At first it may sound somewhat novel to demand that a slowly progressing ailment like phthisis should be notified as if it were liable to become an epidemic disease; but, after all, we may fairly inquire whether the purpose of notification is not the prevention of any disease that could be arrested by early intelligence of its existence being sent to the health officer, nor would there be much difficulty in obtaining the notification of phthisis. Although phthisis is not directly contagious, there would be nothing unreasonable in classing it with other diseases that need special measures to prevent its spread.

(2) *Disinfection.*—After receiving notice of a case of tuberculosis, the next step to be taken by a local authority would be to ascertain whether proper care is or can be taken to prevent injury to the public health. In the case of well-to-do persons the information given by the medical attendant would be sufficient, but where the case is that of a poor person it should be visited, and the local authority should see to the regular cleansing and whitewashing of the premises, and to the disposal of excretions, especially of the expectorated matter. If necessary, disinfection by sulphur and the steaming of clothes should be carried out. Paper spittoons that can be burnt should be insisted upon. After death, also, measures should be taken for the cleansing and disinfection of house, bedding, and clothes.

(3) *Hospital Accommodation.*—There would next come the question of the propriety or possibility of removing the sick person to hospital. So long as he (or she) could work, and so long as he would consent to use the necessary means for destroying the infective material, it would be unnecessary to do more than I have already indicated; but when the patient becomes unable to follow his employment, and the family are obliged to seek for assistance from the parish, he has a claim to be received into the workhouse hospital, and such an asylum should be offered him, and should be made as little humiliating and as free from ignominy as possible.

(4) But it is probably to general sanitary measures that we must look for any large reduction in the rate of mortality from tubercle. It has been found that deep and thorough drainage of the subsoil will greatly diminish this mortality. In the case of Salisbury, as you are probably aware, it was reduced by one-half, and similar reports have come from other towns; and though the same result has not always been obtained elsewhere, there can be no doubt as to the importance both of draining and concreting the foundations of dwelling-houses, so as to prevent organic vapours from rising along with the ground air into living-rooms.

It is for this reason that I have ventured to suggest that where consumption is prevalent there must exist some special nutriment which either (1) serves to prolong the life of the bacillus of tubercle, or (2) which may even increase its virulent properties, this special element in foul air being either the organic matter exhaled from human bodies, or the emanations from polluted ground air from badly drained subsoils. I should imagine that either of these hypotheses might account for the result, and certainly in the few experiments which I have carried out to find the conditions that modify the virulence of the bacillus it was proved that foul air caused the organism to retain its power for evil much longer than when it was exposed to some fresh air and light.

It is possible that these may be regarded as somewhat strong proposals, but at least they have the merit that they may all be put in force without any material increase in the powers now possessed by local authorities. The only thing needed to enable them to be carried out in their entirety is a powerful public opinion to back them up. When people generally, and especially the working classes, realize that a large part of their sickness and consequent loss of time and money is due to their neglect, they will unquestionably be on our side. The undertaking possesses, moreover, the further merit that not only will all this sanitary improvement prevent consumption and other tubercular diseases by doing away with the sources of infection, but it will also prevent them by raising the general standard of health amongst town dwellers. It will so strengthen those who are already predisposed to the disease that they will more readily throw off any stray germs of tubercle that may find an entrance into their bodies. It will conduce to spontaneous cure, will prevent recurrence of the disease, and will ward off attacks from those who are now healthy.

Prof. Finkelnburg, of Bonn, read a paper "On the Influence of Soil on the Spread of Tuberculous Diseases."

He showed on a large map of Germany that the localities where phthisis was most prevalent were those in which there was a moory soil with stagnating and high-standing ground water; such as some districts in the north-western provinces, in the Rhenish province, in Upper Bavaria, and in some parts of Silesia. These facts agree with the conclusions of Bowditch and Buchanan. Overcrowding did not appear to have much influence on the spread of phthisis.

Dr. J. Edward Squire, of London, read a paper entitled, "To what extent can Legislation assist in diminishing the Prevalence of Consumption and other Tubercular Diseases."

Dr. Squire considered that the danger of infection increased with the close crowding of the sick and healthy, and with deficient ventilation; and that by sanitary improvements this danger might be obviated. There ought also to be a proper supervision of food (meat and milk) obtained from tuberculous cattle. Trades in relation to phthisis were also discussed.

Dr. Gibert, of Havre, followed with a paper entitled "De la distribution géographique de la Phthisie pulmonaire dans la ville de Havre: Rapports de la Phthisie avec la densité de la population, avec l'alcoolisme, et avec la misère." Dr. Gibert thought from his observations that overcrowding was a great factor in the etiology of phthisis: but that alcoholism played a much greater part, and poverty was also a factor. He showed on a map the distribution of phthisis in Havre.

Sir John Banks, of Dublin, who spoke in the discussion, mentioned that the sanitary improvements undertaken in Dublin had produced a great diminution of disease. Practice both in hospital and private had demonstrated this to him.

Mr. Weaver, of London, and Dr. B. O'Connor also took part in the discussion.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Aërial Roots of the Mangrove.

In your note on a recent meeting of the Royal Botanic Society (July 30, p. 304), it is stated that the only explanation yet offered of the erect aërial roots of *Avicennia nivea* is that of detaining the *débris* and preventing the soil from being washed away. Without in any way detracting from the ingenuity and probability of Mr. Sowerby's explanation, it can hardly be admitted that this is the only explanation that has as yet been proposed. The peculiarities, both structural and physiological, of the mangrove-vegetation of the swamps of the Malayan Archipelago have been, during recent years, a special subject of investigation by botanists located at the Botanical Laboratory at Buitenzorg; the most recent and most important addition to its literature being comprised in the 22nd Heft of Luerssen and Haenlein's

Digitized by Google

"Bibliotheca Botanica," illustrated by eleven fine plates, by Herr G. Karsten. Herr Karsten points out that, in addition to the obvious mechanical function of these roots, serving as a supporting organ to attach the trees more firmly to the very loose soil in which they grow—this is especially observable in *Rhizophora mangle*—there is another important function performed by them, at least in a large number of the trees which make up the mangrove-vegetation, though I do not recollect that *Avicennia nivea* is especially mentioned. In the species examined by Karsten, these aërial roots possess very large intercellular spaces, which serve to promote the interchange of gases; and he considers it unquestionable that their chief function is to assist respiration. He therefore proposes for them the term "pneumatophores." It would be interesting to examine the structure of the trees at the Botanic Garden in this respect. All mangrove-trees also contain large quantities of tannin, which is probably serviceable in preventing rotting.

August 1. ALFRED W. BENNETT.

The Tasman Sea.

I SEND you the inclosed copy of a letter from the Secretary of the Admiralty, in case you should consider the matter of sufficient interest for notice in your columns.

A. LIVERSIDGE, Permanent Hon. Sec.
Australasian Association for the Advancement of Science.

The University, Sydney, July 4.

Admiralty, May 19, 1891.

SIR,—With reference to your letter of March 17, forwarding copy of a resolution passed by the Australasian Association for the Advancement of Science at the meeting held at Christchurch, New Zealand, that the name of Tasman Sea should be given to the sea between New Zealand and the islands of the north-west of New Zealand on the one hand and Australia and Tasmania on the other, I am commanded by my Lords Commissioners of the Admiralty to acquaint you that the name will be inserted in Admiralty charts and other publications.

I am, Sir,
Your obedient servant,
EVAN MACGREGOR.

To Prof. Liversidge, M.A., F.R.S.,
The University, Sydney.

Reduplication of Seasonal Growth.

LAST summer I sent you a note on the occurrence of apple-blossoms and the blossoms of the mountain ash in July. Before me now, as I write, is a simple but elegant bouquet containing a beautiful and fragrant corymb of the latter tree in full flower, side by side with one of the ripe scarlet fruit, which the blackbirds have begun to devour. These were cut from one and the self-same tree this morning at the top of my garden; while from an adjoining tree was gathered a twig carrying four pinnate leaves from which all the chlorophyll has disappeared; the phenomena which mark the beginning and the end of the season thus appearing side by side. These trees grows on the Upper Bagshot Sands, and I have no doubt that this reduplication of seasonal growth is due to the later rains developing some centres of flowering energy in the plant, which had remained dormant during the spring owing to deficiency of moisture and warmth.

Wellington College, Berks, August 17. A. IRVING.

Rain-gauges.

I HAVE been using the ordinary Symonds pattern rain-gauge, but find that the percentage of rain collected varies in proportion to the strength of the wind; when this is moderately strong, almost the whole of the rain passes across the top, striking and being retained by vertical surfaces only.

The present method of estimating the rainfall is far from being either correct or uniform, and I should like to ascertain if any gauge has been made with a correctly-proportioned inverted cone, which will collect and compensate for side drive; and, if so, what are the correct proportions. It would appear that either this, or a funnel mounted on gimbals and balanced to face the wind at the correct angle, must be the only correct method to ascertain the actual rainfall. The present apparatus would appear to be crude, untrustworthy, and incapable under any conditions in practice of giving results which are at all trustworthy. THOS. FLETCHER.

Grappenhall House, Grappenhall, near Warrington, August 17.

THE BRITISH ASSOCIATION.

(FROM OUR CORRESPONDENT.)

CARDIFF, *Wednesday Morning.*

THE preparations of the Local Committee are now in an advanced state, and members of the Association are beginning to arrive in considerable numbers.

A change has been made in the position of the Reception Room, which is now located entirely in the Drill Hall, the Town Hall having had to be abandoned for that purpose owing to the impossibility of making adequate provision for the accommodation of the large number of guests expected. The Drill Hall is a large building, and has been divided into two parts by a screen, which also serves the purpose of a notice-board. On the entrance side are the offices for various purposes, post and excursions; and at a central oval counter, all other requirements relating to tickets, reserved seats, publications, and lodgings are attended to by a numerous staff of clerks.

Beyond the screen the hall has been fitted up as a drawing-room, and from this lead off smaller rooms for ladies, the press, and smokers. Separated from the drawing-room by a passage is the gun-room, from which everything has been removed, and tables laid down so as to convert it into a dining-room.

The President's address will be given in the Park Hall, this evening, and for the half-hour of waiting before the business commences Mr. T. E. Aylward will give a recital upon the fine organ in that hall. It is understood that Lord Bute, as Mayor of Cardiff, will at the outset welcome the Association in the name of the town of Cardiff.

The *conversazioni* will also be given in the same hall, and from 8.30 to 9 p.m., Lord Bute, as Chairman of the Local Committee, accompanied by Lady Bute, will receive the guests. At 9.30 p.m. an exhibition of views will be given by the lime-light, amongst them some fine ones, by Mr. M. Stirrup, of the limestone region of Languedoc. Amongst other attractions will be taking impressions of finger-tips, by Sergeant Randall (Mr. F. Galton's assistant); a model of the moon, shown by the Astronomer-Royal of Scotland; drawings in black and white of the Himalayas, by Col. Tanner; a collection of old local maps and atlases, by Mr. O. H. Jones; the Eisteddfod concert given at Swansea transmitted by telephone, by Mr. Gavey; and numerous other objects of interest.

Arrangements have been made for military and vocal music.

No alteration has been made in the Section rooms from that mentioned in our former article.

The publications of the Local Committee are ready for distribution, and comprise the local hand-book of 240 pages dealing with the archæology of the land of Morgan, the education, botany, geology, industries, and topography of Cardiff; the excursions-guide containing a map of the district on a scale of four miles to the inch, and two maps on a larger scale, one of the Bute Docks, and the other of the Barry Dock. The excursions number twenty in all—twelve are arranged for Saturday, the 22nd, and eight for Thursday, the 27th; and moderately detailed descriptions of each are given in the guide to the excursions.

The local programme, and the list of lodgings and hotels, are the remaining publications of the Committee. The total number of members of all classes who have taken out tickets for the meeting was, at 6 p.m. yesterday, over 900.

The President's address is as follows:—

INAUGURAL ADDRESS BY WILLIAM HUGGINS, ESQ., D.C.L. (OXON.), LL.D. (CANTAB., EDIN., ET DUBL.), PH.D. (LUGD. BAT.), F.R.S., F.R.A.S., HON. F.R.S.E., &C., CORRESPONDANT DE L'INSTITUT DE FRANCE, PRESIDENT.

IT is now many years since this Association has done honour to the science of Astronomy in the selection of its President.

Since Sir George Airy occupied the chair in 1851, and the late Lord Wrottesley nine years later, in 1860, other sciences have been represented by the distinguished men who have presided over your meetings.

The very remarkable discoveries in our knowledge of the heavens which have taken place during this period of thirty years—one of amazing and ever-increasing activity in all branches of science—have not passed unnoticed in the addresses of your successive Presidents; still it seems to me fitting that I should speak to you to-night chiefly of those newer methods of astronomical research which have led to those discoveries, and which have become possible by the introduction since 1860 into the observatory of the spectroscope and the modern photographic plate.

In 1866 I had the honour of bringing before this Association, at one of the evening lectures, an account of the first fruits of the novel and unexpected advances in our knowledge of the celestial bodies which followed rapidly upon Kirchhoff's original work on the solar spectrum and the interpretation of its lines.

Since that time a great harvest has been gathered in the same field by many reapers. Spectroscopic astronomy has become a distinct and acknowledged branch of the science, possessing a large literature of its own and observatories specially devoted to it. The more recent discovery of the gelatine dry plate has given a further great impetus to this modern side of astronomy, and has opened a pathway into the unknown of which even an enthusiast thirty years ago would scarcely have dared to dream.

In no science, perhaps, does the sober statement of the results which have been achieved appeal so strongly to the imagination, and make so evident the almost boundless powers of the mind of man. By means of its light alone to analyze the chemical nature of a far distant body; to be able to reason about its present state in relation to the past and future; to measure within an English mile or less per second the otherwise invisible motion which it may have towards or from us; to do more, to make even that which is darkness to our eyes light, and from vibrations which our organs of sight are powerless to perceive to evolve a revelation in which we see mirrored some of the stages through which the stars may pass in their slow evolutional progress—surely the record of such achievements, however poor the form of words in which they may be described, is worthy to be regarded as the scientific epic of the present century.

I do not purpose to attempt a survey of the progress of spectroscopic astronomy from its birth at Heidelberg in 1859, but to point out what we do know at present, as distinguished from what we do not know, of a few only of its more important problems, giving a prominent place, in accordance with the traditions of this chair, to the work of the last year or two.

In the spectroscope itself advances have been made by Lord Rayleigh by his discussion of the theory of the instrument, and by Prof. Rowland in the construction of concave gratings.

Lord Rayleigh has shown that there is not the necessary connection, sometimes supposed, between dispersion and resolving power, as besides the prism or grating other details of construction and of adjustment of a spectroscope must be taken into account.

The resolving power of the prismatic spectroscope is proportional to the length of path in the dispersive medium. For the heavy flint glass used in Lord Rayleigh's experiments, the thickness necessary to resolve the sodium lines, came out 1·02 cm. If this be taken as a unit, the resolving power of a prism of similar glass will be in the neighbourhood of the sodium lines equal to the number of centimetres of its thickness. In other parts of the spectrum the resolving power will vary inversely as the third power of the wave-length, so that it will be eight times as great in the violet as in the red. The resolving power of a spectroscope is therefore proportional to the total thickness of the dispersive material in use, irrespective of the number, the angles, or the setting of the separate prisms into which, for the sake of convenience, it may be distributed.

The resolving power of a grating depends upon the total number of lines on its surface, and the order of spectrum in use; about 1000 lines being necessary to resolve the sodium lines in the first spectrum.

As it is often of importance in the record of observations to state the efficiency of the spectroscope with which they were made, Prof. Schuster has proposed the use of a unit of purity as well as of resolving power, for the full resolving power of a spectroscope is realized in practice only when a sufficiently narrow slit is used. The unit of purity also is to stand for the separation of two lines differing by one-thousandth of their own wave-length; about the separation of the sodium pair at D.

A further limitation may come in from the physiological fact that, as Lord Rayleigh has pointed out, the eye, when its full aperture is used, is not a perfect instrument. If we wish to realize the full resolving power of a spectroscope, therefore, the emergent beam must not be larger than about one-third of the opening of the pupil.

Up to the present time the standard of reference for nearly all spectroscopic work continues to be Ångström's map of the solar spectrum, and his scale based upon his original determinations of absolute wave-length. It is well known, as was pointed out by Thalén in his work on the spectrum of iron, in 1884, that Ångström's figures are slightly too small, in consequence of an error existing in a standard metre used by him. The corrections for this have been introduced into the tables of the wave-lengths of terrestrial spectra collected and revised by a Committee of this Association from 1885 to 1887. Last year the Committee adedd a table of corrections to Rowland's scale.

The inconvenience caused by a change of standard scale is, for a time at least, considerable; but there is little doubt that in the near future Rowland's photographic map of the solar spectrum, and his scale based on the determinations of absolute wave-length by Pierce and Bell, or the Potsdam scale based on original determinations by Müller and Kempf, which differs very slightly from it, will come to be exclusively adopted.

The great accuracy of Rowland's photographic map is due chiefly to the introduction by him of concave gratings, and of a method for their use by which the problem of the determination of relative wave-lengths is simplified to measures of coincidences of the lines in different spectra by a micrometer.

The concave grating and its peculiar mounting, in which no lenses or telescope are needed, and in which all the spectra are in focus together, formed a new departure of great importance in the measurement of spectral lines. The valuable method of photographic sensitizers for different parts of the spectrum has enabled Prof. Rowland to include in his map the whole visible solar spectrum, as well as the ultra-violet portion as far as it can get through our atmosphere. Some recent photographs of the solar spectrum, which include A, by Mr. George Higgs, are of great technical beauty.

During the past year the results of three independent researches have appeared, in which the special object of the observers has been to distinguish the lines which are due to our atmosphere from those which are truly solar—the maps of M. Thollon, which, owing to his lamented death just before their final completion, have assumed the character of a memorial of him; maps by Dr. Becker; and sets of photographs of a high and a low sun by Mr. McClean.

At the meeting of this Association in Bath, M. Janssen gave an account of his own researches on the terrestrial lines of the solar spectrum which owe their origin to the oxygen of our atmosphere. He discovered the remarkable fact that, while one class of bands varies as the density of the gas, other diffuse bands vary as the square of the density. These observations are in accordance with the work of Egoroff and of Olszewski, and of Liveing and Dewar on condensed oxygen. In some recent experiments Olszewski, with a layer of liquid oxygen 30 millimetres thick, saw, as well as four other bands, the band coincident with Fraunhofer's A; a remarkable instance of the persistence of absorption through a great range of temperature. The light which passed through the liquid oxygen had a light blue colour resembling that of the sky.

Of not less interest are the experiments of Knut Ångström, which show that the carbonic acid and aqueous vapour of the atmosphere reveal their presence by dark bands in the invisible infra-red region, at the positions of bands of emission of these substances.

It is now some thirty years since the spectroscope gave us for the first time certain knowledge of the nature of the heavenly bodies, and revealed the fundamental fact that terrestrial matter

Digitized by Google

is not peculiar to the solar system, but is common to all the stars which are visible to us.

In the case of a star such as Capella, which has a spectrum almost identical with that of the sun, we feel justified in concluding that the matter of which it is built up is similar, and that its temperature is also high, and not very different from the solar temperature. The task of analyzing the stars and nebulæ becomes, however, one of very great difficulty when we have to do with spectra differing from the solar type. We are thrown back upon the laboratory for the information necessary to enable us to interpret the indications of the spectroscope as to the chemical nature, the density and pressure, and the temperature of the celestial masses.

What the spectroscope immediately reveals to us are the waves which were set up in the ether filling all interstellar space, years or hundreds of years ago, by the motions of the molecules of the celestial substances. As a rule, it is only when a body is gaseous and sufficiently hot that the motions within its molecules can produce bright lines and a corresponding absorption. The spectra of the heavenly bodies are, indeed, to a great extent absorption spectra, but we have usually to study them through the corresponding emission spectra of bodies brought into the gaseous form and rendered luminous by means of flames or of electric discharges. In both cases, unfortunately, as has been shown recently by Profs. Liveing and Dewar, Wüllner, E. Wiedemann, and others, there appears to be no certain direct relation between the luminous radiation as shown in the spectroscope and the temperature of the flame, or of the gaseous contents of the vacuum tube—that is, in the usual sense of the term as applied to the mean motion of all the molecules. In both cases, the vibratory motions within the molecules to which their luminosity is due are almost always much greater than would be produced by encounters of molecules having motions of translation no greater than the average motions which characterize the temperature of the gases as a whole. The temperature of a vacuum tube through which an electric discharge is taking place may be low, as shown by a thermometer, quite apart from the consideration of the extreme smallness of the mass of gas, but the vibrations of the luminous molecules must be violent in whatever way we suppose them to be set up by the discharge; if we take Schuster's view that comparatively few molecules are carrying the discharge, and that it is to the fierce encounters of these alone that the luminosity is due, then if all the molecules had similar motions, the temperature of the gas would be very high.

So in flames where chemical changes are in progress, the vibratory motions of the molecules which are luminous may be, in connection with the energy set free in these changes, very different from those corresponding to the mean temperature of the flame.

Under the ordinary conditions of terrestrial experiments, therefore, the temperature or the mean *vis viva* of the molecules may have no direct relation to the total radiation, which, on the other hand, is the sum of the radiation due to each luminous molecule.

These phenomena have recently been discussed by Ebert from the standpoint of the electro-magnetic theory of light.

Very great caution is therefore called for when we attempt to reason by the aid of laboratory experiments to the temperature of the heavenly bodies from their radiation, especially on the reasonable assumption that in them the luminosity is not ordinarily associated with chemical changes or with electrical discharges; but is due to a simple glowing from the ultimate conversion into molecular motion of the gravitational energy of shrinkage.

In a recent paper Stas maintains that electric spectra are to be regarded as distinct from flame spectra, and from researches of his own, that the pairs of lines of the sodium spectrum other than D are produced only by disruptive electric discharges. As these pairs of lines are found reversed in the solar spectrum, he concludes that the sun's radiation is due mainly to electric discharges. But Wolf and Diacon, and later, Watts, observed the other pairs of lines of the sodium spectrum when the vapour was raised above the ordinary temperature of the Bunsen flame. Recently, Liveing and Dewar saw easily, besides D, the citron and green pairs, and sometimes the blue pair and the orange pair, when hydrogen charged with sodium vapour was burning at different pressures in oxygen. In the case of sodium vapour, therefore, and presumably in all other vapours and gases, it is a matter of indifference whether the necessary vibratory motion of the molecules is produced by electric discharges or by flames. The presence of lines in the solar spectrum which we can only produce electrically, is an indication, however, as Stas points out, of the high temperature of the sun.

We must not forget that the light from the heavenly bodies may consist of the combined radiations of different layers of gas at different temperatures, and possibly be further complicated to an unknown extent by the absorption of cooler portions of gas outside.

Not less caution is needed if we endeavour to argue from the broadening of lines and the coming in of a continuous spectrum as to the relative pressure of the gas in the celestial atmospheres. On the one hand, it cannot be gainsaid that in the laboratory the widening of the lines in a Plücker's tube follows upon increasing the density of the residue of hydrogen in the tube, when the vibrations are more frequently disturbed by fresh encounters, and that a broadening of the sodium lines in a flame at ordinary pressure is produced by an increase of the quantity of sodium in the flame; but it is doubtful if pressure, as distinguished from quantity, does produce an increase of the breadth of the lines. An individual molecule of sodium will be sensibly in the same condition, considering the relatively enormous number of the molecules of the other gases, whether the flame is scantily or copiously fed with the sodium salt. With a small quantity of sodium vapour the intensity will be feeble except near the maximum of the lines; when, however, the quantity is increased, the comparative transparency on the sides of the maximum will allow the light from the additional molecules met with in the path of the visual ray to strengthen the radiation of the molecules farther back, and so increase the breadth of the lines.

In a gaseous mixture it is found, as a rule, that at the same pressure or temperature, as the encounters with similar molecules become fewer, the spectral lines will be affected as if the body were observed under conditions of reduced quantity or temperature.

In their recent investigation of the spectroscopic behaviour of flames under various pressures up to forty atmospheres, Profs. Liveing and Dewar have come to the conclusion that, though the prominent feature of the light emitted by flames at high pressure appears to be a strong continuous spectrum, there is not the slightest indication that this continuous spectrum is produced by the broadening of the lines of the same gases at low pressure. On the contrary, photometric observations of the brightness of the continuous spectrum, as the pressure is varied, show that it is mainly produced by the mutual action of the molecules of a gas. Experiments on the sodium spectrum were carried up to a pressure of forty atmospheres without producing any definite effect on the width of the lines which could be ascribed to the pressure. In a similar way the lines of the spectrum of water showed no signs of expansion up to twelve atmospheres; though more intense than at ordinary pressure, they remained narrow and clearly defined.

It follows, therefore, that a continuous spectrum cannot be considered, when taken alone, as a sure indication of matter in the liquid or the solid state. Not only, as in the experiments already mentioned, such a spectrum may be due to gas when under pressure, but, as Maxwell pointed out, if the thickness of a medium, such as sodium vapour, which radiates and absorbs different kinds of light, be very great, and the temperature high, the light emitted will be of exactly the same composition as that emitted by lamp-black at the same temperature, for the radiations which are feebly emitted will be also feebly absorbed, and can reach the surface from immense depths. Schuster has shown that oxygen, even in a partially exhausted tube, can give a continuous spectrum when excited by a feeble electric discharge.

Compound bodies are usually distinguished by a banded spectrum; but, on the other hand, such a spectrum does not necessarily show the presence of compounds—that is, of molecules containing different kinds of atoms—but simply of a more complex molecule, which may be made up of similar atoms, and be, therefore, an allotropic condition of the same body. In some cases—for example, in the diffuse bands of the absorption spectrum of oxygen—the bands may have an intensity proportional to the square of the density of the gas, and may be due either to the formation of more complex molecules of the gas with increase of pressure, or it may be to the constraint to which the molecules are subject during their encounter with one another.

It may be thought that at least in the coincidences of bright lines we are on the solid ground of certainty, since the length of

the waves set up in the ether by a molecule, say of hydrogen, is the most fixed and absolutely permanent quantity in nature, and is so of physical necessity, for with any alteration the molecule would cease to be hydrogen.

Such would be the case if the coincidence were certain; but an absolute coincidence can be only a matter of greater or less probability, depending on the resolving power employed, on the number of the lines which correspond, and on their characters. When the coincidences are very numerous, as in the case of iron and the solar spectrum, or the lines are characteristically grouped, as in the case of hydrogen and the solar spectrum, we may regard the coincidence as certain; but the progress of science has been greatly retarded by resting important conclusions upon the apparent coincidence of single lines, in spectroscopes of very small resolving power. In such cases, unless other reasons supporting the coincidence are present, the probability of a real coincidence is almost too small to be of any importance, especially in the case of a heavenly body which may have a motion of approach or of recession of unknown amount.

But even here we are met by the confusion introduced by multiple spectra, corresponding to different molecular groupings of the same substance; and, further, to the influence of substances in vapour upon each other; for when several gases are present together, the phenomena of radiation and reversal by absorption are by no means the same as if the gases were free from each other's influence, and especially is this the case when they are illuminated by an electric discharge.

I have said as much as time will permit, and I think indeed sufficient, to show that it is only by the laborious and slow process of most cautious observation that the foundations of the science of celestial physics can be surely laid. We are at present in a time of transition, when the earlier, and, in the nature of things, less precise, observations are giving place to work of an order of accuracy much greater than was formerly considered attainable with objects of such small brightness as the stars.

The accuracy of the earlier determinations of the spectra of the terrestrial elements are in most cases insufficient for modern work on the stars as well as on the sun. They fall much below the scale adopted in Rowland's map of the sun, as well as below the degree of accuracy attained at Potsdam by photography in a part of the spectrum for the brighter stars. Increase of resolving power very frequently breaks up into groups, in the spectra of the sun and stars, the lines which had been regarded as single, and their supposed coincidences with terrestrial lines fall to the ground. For this reason many of the early conclusions, based on observation as good as it was possible to make at the time with the less powerful spectroscopes then in use, may not be found to be maintained under the much greater resolving power of modern instruments.

The spectroscope has failed as yet to interpret for us the remarkable spectrum of the Aurora Borealis. Undoubtedly in this phenomenon portions of our atmosphere are lighted up by electric discharges: we should expect, therefore, to recognize the spectra of the gases known to be present in it. As yet we have not been able to obtain similar spectra from these gases artificially, and especially we do not know the origin of the principal line in the green, which often appears alone, and may have, therefore, an origin independent of that of the other lines. Recently the suggestion has been made that the aurora is a phenomenon produced by the dust of meteors and falling stars, and that near positions of certain auroral lines or flutings of manganese, lead, barium, thallium, iron, &c., are sufficient to justify us in regarding meteoric dust in the atmosphere as the origin of the auroral spectrum. Liveing and Dewar have made a conclusive research on this point, by availing themselves of the dust of excessive minuteness thrown off from the surface of electrodes of various metals and meteorites by a disruptive discharge, and carried forward into the tube of observation by a more or less rapid current of air or other gas. These experiments prove that metallic dust, however fine, suspended in a gas will not act like gaseous matter in becoming luminous with its characteristic spectrum in an electric discharge similar to that of the aurora. Prof. Schuster has suggested that the principal line may be due to some very light gas which is present in too small a proportion to be detected by chemical analysis or even by the spectroscope in the presence of the other gases near the earth, but which at the height of the auroral discharges is in a sufficiently greater relative proportion to give a spectrum. Lemström, indeed, states that he saw this line in the silent discharge of a Holtz machine on a mountain in Lapland. The lines may not have been obtained in our laboratories from the atmospheric gases on account of the difficulty of reproducing in tubes with sufficient nearness the conditions under which the auroral discharges take place.

In the spectra of comets the spectroscope has shown the presence of carbon presumably in combination with hydrogen, and also sometimes with nitrogen; and in the case of comets approaching very near the sun, the lines of sodium, and other lines which have been supposed to belong to iron. Though the researches of Prof. H. A. Newton and of Prof. Schiaparelli leave no doubt of the close connection of comets with corresponding periodic meteor swarms, and therefore of the probable identity of cometary matter with that of meteorites, with which the spectroscopic evidence agrees, it would be perhaps unwise at present to attempt to define too precisely the exact condition of the matter which forms the nucleus of the comet. In any case the part of the light of the comet which is not reflected solar light can scarcely be attributed to a high temperature produced by the clashing of separate meteoric stones set up within the nucleus by the sun's disturbing force. We must look rather to disruptive electric discharges, produced probably by processes of evaporation due to increased solar heat, which would be amply sufficient to set free portions of the occluded gases into the vacuum of space. May it be that these discharges are assisted, and indeed possibly increased, by the recently discovered action of the ultra-violet part of the sun's light? Lenard and Wolfe have shown that ultra-violet light can produce a discharge from a negatively electrified piece of metal, while Hallwachs and Righi have shown further that ultra-violet light can even charge positively an unelectrified piece of metal. Similar actions on cometary matter, unscreened as it is by an absorptive atmosphere, at least of any noticeable extent, may well be powerful when a comet approaches the sun, and help to explain an electrified condition of the evaporated matter which would possibly bring it under the sun's repulsive action. We shall have to return to this point in speaking of the solar corona.

A very great advance has been made in our knowledge of the constitution of the sun by the recent work at the Johns Hopkins University by means of photography and concave gratings, in comparing the solar spectrum, under great resolving power, directly with the spectra of the terrestrial elements. Prof. Rowland has shown that the lines of thirty-six terrestrial elements at least are certainly present in the solar spectrum, while eight others are doubtful. Fifteen elements, including nitrogen as it shows itself under an electric discharge in a vacuum tube, have not been found in the solar spectrum. Some ten other elements, inclusive of oxygen, have not yet been compared with the sun's spectrum.

Rowland remarks that of the fifteen elements named as not found in the sun, many are so classed because they have few strong lines, or none at all, in the limit of the solar spectrum as compared by him with the arc. Boron has only two strong lines. The lines of bismuth are compound and too diffuse. Therefore even in the case of these fifteen elements there is little evidence that they are really absent from the sun.

It follows that if the whole earth were heated to the temperature of the sun, its spectrum would resemble very closely the solar spectrum.

Rowland has not found any lines common to several elements, and in the case of some accidental coincidences, more accurate investigation reveals some slight difference of wave-length or a common impurity. Further, the relative strength of the lines in the solar spectrum is generally, with a few exceptions, the same as that in the electric arc, so that Rowland considers that his experiments show "very little evidence" of the breaking up of the terrestrial elements in the sun.

Stas in a recent paper gives the final results of eleven years of research on the chemical elements in a state of purity, and on the possibility of decomposing them by the physical and chemical forces at our disposal. His experiments on calcium, strontium, lithium, magnesium, silver, sodium, and thallium, show that these substances retain their individuality under all conditions, and are unalterable by any forces that we can bring to bear upon them.

Prof. Rowland looks to the solar lines which are unaccounted for as a means of enabling him to discover such new terrestrial elements as still lurk in rare minerals and earths, by confronting their spectra directly with that of the sun. He has already resolved yttrium spectroscopically into three components, and

actually into two. The comparison of the results of this independent analytical method with the remarkable but different conclusions to which M. Lecoq de Boisbaudran and Mr. Crookes have been led respectively, from spectroscopic observation of these bodies when glowing under molecular bombardment in a vacuum tube, will be awaited with much interest. It is worthy of remark that, as our knowledge of the spectrum of hydrogen in its complete form came to us from the stars, it is now from the sun that chemistry is probably about to be enriched by the discovery of new elements.

In a discussion in the Bakerian Lecture for 1885 of what we knew up to that time of the sun's corona, I was led to the conclusion that the corona is essentially a phenomenon similar in the cause of its formation to the tails of comets—namely, that it consists for the most part probably of matter going from the sun under the action of a force, possibly electrical, which varies as the surface, and can therefore in the case of highly attenuated matter easily master the force of gravity even near the sun. Though many of the coronal particles may return to the sun, those which form the long rays or streamers do not return; they separate and soon become too diffused to be any longer visible, and may well go to furnish the matter of the zodiacal light, which otherwise has not received a satisfactory explanation. And further, if such a force exist at the sun, the changes of terrestrial magnetism may be due to direct electric action, as the earth moves through lines of inductive force.

These conclusions appear to be in accordance broadly with the lines along which thought has been directed by the results of subsequent eclipses. Prof. Schuster takes an essentially similar view, and suggests that there may be a direct electric connection between the sun and the planets. He asks further whether the sun may not act like a magnet in consequence of its revolution about its axis. Prof. Bigelow has recently treated the coronal forms by the theory of spherical harmonics, on the supposition that we see phenomena similar to those of free electricity, the rays being lines of force, and the coronal matter discharged from the sun, or at least arranged or controlled by these forces. At the extremities of the streams for some reasons the repulsive power may be lost, and gravitation set in, bringing the matter back to the sun. The matter which does leave the sun is persistently transported to the equatorial plane of the corona; in fact, the zodiacal light may be the accumulation at great distances from the sun along this equator of such like material. Photographs on a larger scale will be desirable for the full development of the conclusions which may follow from this study of the curved forms of the coronal structure. Prof. Schaeberle, however, considers that the coronal phenomena may be satisfactorily accounted for on the supposition that the corona is formed of streams of matter ejected mainly from the spot zones with great initial velocities, but smaller than 382 miles per second. Further that the different types of the corona are due to the effects of perspective on the streams from the earth's place at the time relatively to the plane of the solar equator.

Of the physical and the chemical nature of the coronal matter we know very little. Schuster concludes, from an examination of the eclipses of 1882, 1883, and 1886, that the continuous spectrum of the corona has the maximum of actinic intensity displaced considerably towards the red when compared with the spectrum of the sun, which shows that it can only be due in small part to solar light scattered by small particles. The lines of calcium and of hydrogen do not appear to form part of the normal spectrum of the corona. The green coronal line has no known representative in terrestrial substances, nor has Schuster been able to recognize any of our elements in the other lines of the corona.

The spectra of the stars are almost infinitely diversified, yet they can be arranged with some exceptions in a series in which the adjacent spectra, especially in the photographic region, are scarcely distinguishable, passing from the bluish-white stars like Sirius, through stars more or less solar in character, to stars with banded spectra, which divide themselves into two apparently independent groups, according as the stronger edge of the bands is towards the red or the blue. In such an arrangement the sun's place is towards the middle of the series.

At present a difference of opinion exists as to the direction in the series in which evolution is proceeding, whether by further condensation white stars pass into the orange and red stages, or whether these more coloured stars are younger and will become white by increasing age. The latter view was suggested by Johnstone Stoney in 1867.

About ten years ago Ritter in a series of papers discussed the behaviour of gaseous masses during condensation, and the probable resulting constitution of the heavenly bodies. According to him, a star passes through the orange and red stages twice: first during a comparatively short period of increasing temperature, which culminates in the white stage, and a second time during a more prolonged stage of gradual cooling. He suggested that the two groups of banded stars may correspond to these different periods: the young stars being those in which the stronger edge of the dark band is towards the blue, the other banded stars, which are relatively less luminous and few in number, being those which are approaching extinction through age.

Recently a similar evolutional order has been suggested, which is based upon the hypothesis that the nebulæ and stars consist of colliding meteoric stones in different stages of condensation.

More recently the view has been put forward that the diversified spectra of the stars do not represent the stages of an evolutional progress, but are due for the most part to differences of original constitution.

The few minutes which can be given to this part of the address are insufficient for a discussion of these different views. I purpose, therefore, to state briefly, and with reserve, as the subject is obscure, some of the considerations from the characters of their spectra which appeared to me to be in favour of the evolutional order in which I arranged the stars from their photographic spectra in 1879. This order is essentially the same as Vogel had previously proposed in his classification of the stars in 1874, in which the white stars, which are most numerous, represent the early adult and most persistent stage of stellar life; the solar condition that of full maturity and of commencing age; while in the orange and red stars with banded spectra we see the setting in and advance of old age. But this statement must be taken broadly, and not as asserting that all stars, however different in mass and possibly to some small extent in original constitution, exhibit one invariable succession of spectra.

In the spectra of the white stars the dark metallic lines are relatively inconspicuous, and occasionally absent, at the same time that the dark lines of hydrogen are usually strong, and more or less broad, upon a continuous spectrum, which is remarkable for its brilliancy at the blue end. In some of these stars the hydrogen and some other lines are bright, and sometimes variable.

As the greater or less prominence of the hydrogen lines, dark or bright, is characteristic of the white stars as a class, and diminishes gradually with the incoming and increase in strength of the other lines, we are probably justified in regarding it as due to some conditions which occur naturally during the progress of stellar life, and not to a peculiarity of original constitution.

To produce a strong absorption-spectrum a substance must be at the particular temperature at which it is notably absorptive; and, further, this temperature must be sufficiently below that of the region behind from which the light comes for the gas to appear, so far as its special rays are concerned, as darkness upon it. Considering the high temperature to which hydrogen must be raised before it can show its characteristic emission and absorption, we shall probably be right in attributing the relative feebleness or absence of the other lines, not to the paucity of the metallic vapours, but rather to their being so hot relatively to the substances behind them as to show feebly, if at all, by reversion. Such a state of things would more probably be found, it seems to me, in conditions anterior to the solar stage. A considerable cooling of the sun would probably give rise to banded spectra due to compounds, or to more complex molecules, which might form near the condensing points of the vapours.

The sun and stars are generally regarded as consisting of glowing vapours surrounded by a photosphere where condensation is taking place, the temperature of the photospheric layer from which the greater part of the radiation comes being constantly renewed from the hotter matter within.

At the surface the convection currents would be strong, producing a considerable commotion, by which the different gases would be mixed and not allowed to retain the inequality of proportions at different levels due to their vapour densities.

Now the conditions of the radiating photosphere and those of the gases above it, on which the character of the spectrum of a star depends, will be determined, not alone by temperature, but also by the force of gravity in these regions; this force will be fixed by the star's mass and its stage of condensation, and will become greater as the star continues to condense.

Digitized by Google

In the case of the sun the force of gravity has already become so great at the surface that the decrease of the density of the gases must be extremely rapid, passing in the space of a few miles from atmospheric pressure to a density infinitesimally small; consequently the temperature-gradient at the surface, if determined solely by expansion, must be extremely rapid. The gases here, however, are exposed to the fierce radiation of the sun, and unless wholly transparent would take up heat, especially if any solid or liquid particles were present from condensation or convection currents.

From these causes, within a very small extent of space at the surface of the sun, all bodies with which we are acquainted should fall to a condition in which the extremely tenuous gas could no longer give a visible spectrum. The insignificance of the angle subtended by this space as seen from the earth should cause the boundary of the solar atmosphere to appear defined. If the boundary which we see be that of the sun proper, the matter above it will have to be regarded as in an essentially dynamical condition—an assemblage, so to speak, of gaseous projectiles for the most part falling back upon the sun after a greater or less range of flight. But in any case it is within a space of relatively small extent in the sun, and probably in the other solar stars, that the reversion which is manifested by dark lines is to be regarded as taking place.

Passing backward in the star's life, we should find a gradual weakening of gravity at the surface, a reduction of the temperature-gradient so far as it was determined by expansion, and convection currents of less violence producing less interference with the proportional quantities of gases due to their vapour densities, while the effects of eruptions would be more extensive.

At last we might come to a state of things in which, if the star were hot enough, only hydrogen might be sufficiently cool relatively to the radiation behind to produce a strong absorption. The lower vapours would be protected, and might continue to be relatively too hot for their lines to appear very dark upon the continuous spectrum; besides, their lines might be possibly to some extent effaced by the coming in under such conditions in the vapours themselves of a continuous spectrum.

In such a star the light radiated towards the upper part of the atmosphere may have come from portions lower down of the atmosphere itself, or at least from parts not greatly hotter. There may be no such great difference of temperature of the low and less low portions of the star's atmosphere as to make the darkening effect of absorption of the protected metallic vapours to prevail over the illuminating effect of their emission.

It is only by a vibratory motion corresponding to a very high temperature that the bright lines of the first spectrum of hydrogen can be brought out, and by the equivalence of absorbing and emitting power that the corresponding spectrum of absorption should be produced; yet for a strong absorption to show itself, the hydrogen must be cool relatively to the source of radiation behind it, whether this be condensed particles or gas. Such conditions, it seems to me, should occur in the earlier rather than in the more advanced stages of condensation.

The subject is obscure, and we may go wrong in our mode of conceiving of the probable progress of events, but there can be no doubt that in one remarkable instance the white-star spectrum is associated with an early stage of condensation.

Sirius is one of the most conspicuous examples of one type of this class of stars. Photometric observations combined with its ascertained parallax show that this star emits from forty to sixty times the light of our sun, even to the eye, which is insensible to ultra-violet light, in which Sirius is very rich, while we learn from the motion of its companion that its mass is not much more than double that of our sun. It follows that, unless we attribute to this star an improbably great emissive power, it must be of immense size, and in a much more diffuse and therefore an earlier condition than our sun; though probably at a later stage than those white stars in which the hydrogen lines are bright.

A direct determination of the relative temperature of the photospheres of the stars might possibly be obtained in some cases from the relative position of maximum radiation of their continuous spectra. Langley has shown that through the whole range of temperature on which we can experiment, and presumably at temperatures beyond, the maximum of radiation-power in solid bodies gradually shifts upwards in the spectrum from the infra-red through the red and orange, and that in the sun it has reached the blue.

The defined character, as a rule, of the stellar lines of absorption suggests that the vapours producing them do not at the same time exert any strong power of general absorption. Consequently, we should probably not go far wrong, when the photosphere consists of liquid or solid particles, if we could compare select parts of the continuous spectrum between the stronger lines, or where they are fewest. It is obvious that, if extended portions of different stellar spectra were compared, their true relation would be obscured by the line-absorption.

The increase of temperature, as shown by the rise in the spectrum of the maximum of radiation, may not always be accompanied by a corresponding greater brightness of a star as estimated by the eye, which is an extremely imperfect photometric instrument. Not only is the eye blind to large regions of radiation, but even for the small range of light that we can see the visual effect varies enormously with its colour. According to Prof. Langley, the same amount of energy which just enables us to perceive light in the crimson at A would in the green produce a visual effect 100,000 times greater. In the violet the proportional effect would be 1600, in the blue 62,000, in the yellow 28,000, in the orange 14,000, and in the red 1200. Captain Abney's recent experiments make the sensitiveness of the eye for the green near F to be 750 times greater than for the red about C. It is for this reason, at least in part, that I suggested in 1864, and have since shown by direct observation, that the spectrum of the nebula in Andromeda, and presumably of similar nebulæ, is, in appearance, only wanting in the red.

The stage at which the maximum radiation is in the green, corresponding to the eye's greatest sensitiveness, would be that in which it could be most favourably measured by eye-photometry. As the maximum rose into the violet and beyond, the star would increase in visual brightness, but not in proportion to the increase of energy radiated by it.

The brightness of a star would be affected by the nature of the substance by which the light was chiefly emitted. In the laboratory, solid carbon exhibits the highest emissive power. A stellar stage in which radiation comes, to a large extent, from a photosphere of the solid particles of this substance, would be favourable for great brilliancy. Though the stars are built up of matter essentially similar to that of the sun, it does not follow that the proportion of the different elements is everywhere the same. It may be that the substances condensed in the photospheres of different stars may differ in their emissive powers, but probably not to a great extent.

All the heavenly bodies are seen by us through the tinted medium of our atmosphere. According to Langley, the solar stage of stars is not really yellow, but, even as gauged by our imperfect eyes, would appear bluish-white if we could free ourselves from the deceptive influences of our surroundings.

From these considerations it follows that we can scarcely infer the evolutional stages of the stars from a simple comparison of their eye-magnitudes. We should expect the white stars to be, as a class, less dense than the stars in the solar stage. As great mass might bring in the solar type of spectrum at a relatively earlier time, some of the brightest of these stars may be very massive, and brighter than the sun—for example, the brilliant star Arcturus. For these reasons the solar stars should not only be dense than the white stars, but perhaps, as a class, surpass them in mass and eye-brightness.

It has been shown by Lane that, so long as a condensing gaseous mass remains subject to the laws of a purely gaseous body, its temperature will continue to rise.

The greater or less breadth of the lines of absorption of hydrogen in the white stars may be due to variations of the depth of the hydrogen in the line of sight, arising from the causes which have been discussed. At the sides of the lines the absorption and emission are feebler than in the middle, and would come out more strongly with a greater thickness of gas.

The diversities among the white stars are nearly as numerous as the individuals of the class. Time does not permit me to do more than to record that, in addition to the three sub-classes into which they have been divided by Vogel, Scheiner has recently investigated minor differences as suggested by the character of the third line of hydrogen near G. He has pointed out, too, that so far as his observations go the white stars in the constellation of Orion stand alone, with the exception of Algol, in possessing a dark line in the blue which has apparently the same position as a bright line in the great nebula of the same constellation; and Pickering finds in his photographs of the spectra of these stars dark lines corresponding to the principal lines of the bright-line stars, and the planetary nebulæ with the

Digitized by Google

exception of the chief nebular line. The association of white stars with nebular matter in Orion, in the Pleiades, in the region of the Milky Way, and in other parts of the heavens, may be regarded as falling in with the view that I have taken.

In the stars possibly further removed from the white class than our sun, belonging to the first division of Vogel's third class, which are distinguished by absorption bands with their stronger edge towards the blue, the hydrogen lines are narrower than in the solar spectrum. In these stars the density-gradient is probably still more rapid, the depth of hydrogen may be less, and possibly the hydrogen molecules may be affected by a larger number of encounters with dissimilar molecules. In some red stars with dark hydrocarbon bands, the hydrogen lines have not been certainly observed; if they are really absent, it may be because the temperature has fallen below the point at which hydrogen can exert its characteristic absorption; besides, some hydrogen will have united with the carbon. The coming in of the hydrocarbon bands may indicate a later evolutional stage, but the temperature may still be high, as acetylene can exist in the electric arc.

A number of small stars more or less similar to those which are known by the names of their discoverers, Wolf and Rayet, have been found by Pickering in his photographs. These are remarkable for several brilliant groups of bright lines, including frequently the hydrogen lines and the line D_3, upon a continuous spectrum strong in blue and violet rays, in which are also dark lines of absorption. As some of the bright groups appear in his photographs to agree in position with corresponding bright lines in the planetary nebulæ, Pickering suggests that these stars should be placed in one class with them, but the brightest nebular line is absent from these stars. The simplest conception of their nature would be that each star is surrounded by a nebula, the bright groups being due to the gaseous matter outside the star. Mr. Roberts, however, has not been able to bring out any indication of nebulosity by prolonged exposure. The remarkable star η Argûs may belong to this class of the heavenly bodies.

In the nebulæ, the elder Herschel saw portions of the fiery mist or "shining fluid" out of which the heavens and the earth had been slowly fashioned. For a time this view of the nebulæ gave place to that which regarded them as external galaxies, cosmical "sand-heaps," too remote to be resolved into separate stars; though indeed, in 1858, Mr. Herbert Spencer showed that the observations of nebulæ up to that time were really in favour of an evolutional progress.

In 1864, I brought the spectroscope to bear upon them; the bright lines which flashed upon the eye showed the source of the light to be glowing gas, and so restored these bodies to what is probably their true place, as an early stage of sidereal life.

At that early time our knowledge of stellar spectra was small. For this reason partly, and probably also under the undue influence of theological opinions then widely prevalent, I unwisely wrote in my original paper in 1864, "that in these objects we no longer have to do with a special modification of our own type of sun, but find ourselves in presence of objects possessing a distinct and peculiar plan of structure." Two years later, however, in a lecture before this Association, I took a truer position. "Our views of the universe," I said, "are undergoing important changes; let us wait for more facts, with minds unfettered by any dogmatic theory, and therefore free to receive the teaching, whatever it may be, of new observations."

Let us turn aside for a moment from the nebulæ in the sky to the conclusions to which philosophers had been irresistibly led by a consideration of the features of the solar system. We have before us in the sun and planets obviously not a haphazard aggregation of bodies, but a system resting upon a multitude of relations pointing to a common physical cause. From these considerations Kant and Laplace formulated the nebular hypothesis, resting it on gravitation alone, for at that time the science of the conservation of energy was practically unknown. These philosophers showed how, on the supposition that the space now occupied by the solar system was once filled by a vaporous mass, the formation of the sun and planets could be reasonably accounted for.

By a totally different method of reasoning, modern science traces the solar system backward step by step to a similar state of things at the beginning. According to Helmholtz, the sun's heat is maintained by the contraction of his mass, at the rate of about 220 feet a year. Whether at the present time the sun is getting hotter or colder we do not certainly know. We can reason back to the time when the sun was sufficiently expanded to fill the whole space occupied by the solar system, and was reduced to a great glowing nebula. Though man's life, the life of the race perhaps, is too short to give us direct evidence of any distinct stages of so august a process, still the probability is great that the nebular hypothesis, especially in the more precise form given to it by Roche, does represent broadly, notwithstanding some difficulties, the succession of events through which the sun and planets have passed.

The nebular hypothesis of Laplace requires a rotating mass of fluid which at successive epochs became unstable from excess of motion, and left behind rings, or more probably perhaps lumps, of matter from the equatorial regions.

The difficulties to which I have referred have suggested to some thinkers a different view of things, according to which it is not necessary to suppose that one part of the system gravitationally supports another. The whole may consist of a congeries of discrete bodies even if these bodies be the ultimate molecules of matter. The planets may have been formed by the gradual accretion of such discrete bodies. On the view that the material of the condensing solar system consisted of separate particles or masses, we have no longer the fluid pressure which is an essential part of Laplace's theory. Faye, in his theory of evolution from meteorites, has to throw over this fundamental idea of the nebular hypothesis, and he formulates instead a different succession of events, in which the outer planets were formed last; a theory which has difficulties of its own.

Prof. George Darwin has recently shown, from an investigation of the mechanical conditions of a swarm of meteorites, that on certain assumptions a meteoric swarm might behave as a coarse gas, and in this way bring back the fluid pressure exercised by one part of the system on the other, which is required by Laplace's theory. One chief assumption consists in supposing that such inelastic bodies as meteoric stones might attain the effective elasticity of a high order which is necessary to the theory through the sudden volatilization of a part of their mass at an encounter, by which what is virtually a violent explosive is introduced between the two colliding stones. Prof. Darwin is careful to point out that it must necessarily be obscure as to how a small mass of solid matter can take up a very large amount of energy in a small fraction of a second.

Any direct indications from the heavens themselves, however slight, are of so great value, that I should perhaps in this connection call attention to a recent remarkable photograph, by Mr. Roberts, of the great nebula in Andromeda. On this plate we seem to have presented to us some stage of cosmical evolution on a gigantic scale. The photograph shows a sort of whirlpool disturbance of the luminous matter which is distributed in a plane inclined to the line of sight, in which a series of rings of bright matter separated by dark spaces, greatly foreshortened by perspective, surround a large undefined central mass. We are ignorant of the parallax of this nebula, but there can be little doubt that we are looking upon a system very remote, and therefore of a magnitude great beyond our power of adequate comprehension. The matter of this nebula, in whatever state it may be, appears to be distributed, as in so many other nebulæ, in rings or spiral streams, and to suggest a stage in a succession of evolutional events not inconsistent with that which the nebular hypothesis requires. To liken this object more directly to any particular stage in the formation of the solar system would be "to compare things great with small," and might be indeed to introduce a false analogy; but, on the other hand, we should err through an excess of caution if we did not accept the remarkable features brought to light by this photograph as a presumptive indication of a progress of events in cosmical history following broadly upon the lines of Laplace's theory.

The old view of the original matter of the nebulæ, that it consisted of a "fiery mist,"

> "a tumultuous cloud
> Instinct with fire and nitre,"

fell at once with the rise of the science of thermodynamics. In 1854, Helmholtz showed that the supposition of an original fiery condition of the nebulous stuff was unnecessary, since in the mutual gravitation of widely separated matter we have a store of potential energy sufficient to generate the high temperature of the sun and stars. We can scarcely go wrong in attributing the light of the nebulæ to the conversion of the gravitational energy of shrinkage into molecular motion.

The idea that the light of comets and of nebulæ may be due

Digitized by Google

to a succession of ignited flashes of gas from the encounters of meteoric stones was suggested by Prof. Tait, and was brought to the notice of this Association in 1871 by Sir William Thomson in his Presidential Address.

The spectrum of the bright-line nebulæ is certainly not such a spectrum as we should expect from the flashing by collisions of meteorites similar to those which have been analyzed in our laboratories. The strongest lines of the substances which in the case of such meteorites would first show themselves, iron, sodium, magnesium, nickel, &c., are not those which distinguish the nebular spectrum. On the contrary, this spectrum is chiefly remarkable for a few brilliant lines, very narrow and defined, upon a background of a faint continuous spectrum, which contains numerous bright lines, and probably some lines of absorption.

The two most conspicuous lines have not been interpreted; for though the second line falls near, it is not coincident with a strong double line of iron. It is hardly necessary to say that though the near position of the brightest line to the bright double line of nitrogen, as seen in a small spectroscope in 1864, naturally suggested at that early time the possibility of the presence of this element in the nebulæ, I have been careful to point out, to prevent misapprehension, that in more recent years the nitrogen line and subsequently a lead line have been employed by me solely as fiducial points of reference in the spectrum.

The third line we know to be the second line of the first spectrum of hydrogen. Mr. Keeler has seen the first hydrogen line in the red, and photographs show that this hydrogen spectrum is probably present in its complete form, or nearly so, as we first learnt to know it in the absorption spectrum of the white stars.

We are not surprised to find associated with it the line D_3, near the position of the absent sodium lines, probably due to the atom of some unknown gas, which in the sun can only show itself in the outbursts of highest temperature, and for this reason does not reveal itself by absorption in the solar spectrum.

It is not unreasonable to assume that the two brightest lines, which are of the same order, are produced by substances of a similar nature, in which a vibratory motion corresponding to a very high temperature is also necessary. These substances, as well as that represented by the line D_3, may be possibly some of the unknown elements which are wanting in our terrestrial chemistry between hydrogen and lithium, unless indeed D_3 be on the lighter side of hydrogen.

In the laboratory we must have recourse to the electric discharge to bring out the spectrum of hydrogen; but in a vacuum-tube, though the radiation may be great, from the relative fewness of the luminous atoms or molecules or from some other cause, the temperature of the gas as a whole may be low.

On account of the large extent of the nebulæ, a comparatively small number of luminous molecules or atoms would probably be sufficient to make the nebulæ as bright as they appear to us. On such an assumption the average temperature may be low, but the individual particles, which by their encounters are luminous, must have motions corresponding to a very high temperature, and in this sense be extremely hot.

In such diffuse masses, from the great mean length of free path, the encounters would be rare but correspondingly violent, and tend to bring about vibrations of comparatively short period, as appears to be the case if we may judge by the great relative brightness of the more refrangible lines of the nebular spectrum.

Such a view may perhaps reconcile the high temperature which the nebular spectrum undoubtedly suggests with the much lower mean temperature of the gaseous mass, which we should expect at so early a stage of condensation, unless we assume a very enormous mass; or that the matter coming together had previously considerable motion, or considerable molecular agitation.

The inquisitiveness of the human mind does not allow us to remain content with the interpretation of the present state of the cosmical masses, but suggests the question—

> "What see'st thou else
> In the dark backward and abysm of time?"

What was the original state of things? how has it come about that by the side of ageing worlds we have nebulæ in a relatively younger stage? Have any of them received their birth from dark suns, which have collided into new life, and so belong to a second or later generation of the heavenly bodies?

During the short historic period, indeed, there is no record of such an event; still it would seem to be only through the collision of dark suns, of which the number must be increasing, that a temporary rejuvenescence of the heavens is possible, and by such ebbings and flowings of stellar life that the inevitable end to which evolution in its apparently uncompensated progress is carrying us can, even for a little, be delayed.

We cannot refuse to admit as possible such an origin for nebulæ.

In considering, however, the formation of the existing nebulæ we must bear in mind that, in the part of the heavens within our ken, the stars still in the early and middle stages of evolution exceed greatly in number those which appear to be in an advanced condition of condensation. Indeed, we find some stars which may be regarded as not far advanced beyond the nebular condition.

It may be that the cosmical bodies which are still nebulous owe their later development to some conditions of the part of space where they occur, such as, conceivably, a greater original homogeneity, in consequence of which condensation began less early. In other parts of space condensation may have been still further delayed, or even have not yet begun. It is worthy of remark that these nebulæ group themselves about the Milky Way, where we find a preponderance of the white-star type of stars, and almost exclusively the bright-line stars which Pickering associates with the planetary nebulæ. Further, Dr. Gill concludes, from the rapidity with which they impress themselves upon the plate, that the fainter stars of the Milky Way also, to a large extent, belong to this early type of stars. At the same time other types of stars occur also over this region, and the red hydrocarbon stars are found in certain parts; but possibly these stars may be before or behind the Milky Way, and not physically connected with it.

If light matter be suggested by the spectrum of these nebulæ, it may be asked further, as a pure speculation, whether in them we are witnessing possibly a later condensation of the light matter which had been left behind, at least in a relatively greater proportion, after the first growth of worlds into which the heavier matter condensed, though not without some entanglement of the lighter substances. The wide extent and great diffuseness of this bright-line nebulosity over a large part of the constellation of Orion may be regarded perhaps as pointing in this direction. The diffuse nebulous matter streaming round the Pleiades may possibly be another instance, though the character of its spectrum has not yet been ascertained.

In the planetary nebulæ, as a rule, there is a sensible increase of the faint continuous spectrum, as well as a slight thickening of the bright lines towards the centre of the nebula, appearances which are in favour of the view that these bodies are condensing gaseous masses.

Prof. G. Darwin, in his investigation of the equilibrium of a rotating mass of fluid, found, in accordance with the independent researches of Poincaré, that when a portion of the central body becomes detached through increasing angular velocity, the portion should bear a far larger ratio to the remainder than is observed in the planets and satellites of the solar system, even taking into account heterogeneity from the condensation of the parent mass.

Now this state of things, in which the masses though not equal are of the same order, does seem to prevail in many nebulæ, and to have given birth to a large class of binary stars. Mr. See has recently investigated the evolution of bodies of this class, and points out their radical differences from the solar system in the relatively large mass-ratios of the component bodies, as well as in the high eccentricities of their orbits brought about by tidal friction, which would play a more important part in the evolution of such systems.

Considering the large number of these bodies, he suggests that the solar system should perhaps no longer be regarded as representing celestial evolution in its normal form—

> "A goodly Paterne to whose perfect mould
> He fashioned them . . ."—

but rather as modified by conditions which are exceptional.

It may well be that in the very early stages condensing masses are subject to very different conditions, and that condensation may not always begin at one or two centres, but sometimes set in at a large number of points, and proceed in the different cases along very different lines of evolution.

Besides its more direct use in the chemical analysis of the heavenly bodies, the spectroscope has given to us a great and

Digitized by Google

unexpected power of advance along the lines of the older astronomy. In the future, a higher value may, indeed, be placed upon this indirect use of the spectroscope than upon its chemical revelations.

By no direct astronomical methods could motions of approach or of recession of the stars be even detected, much less could they be measured. A body coming directly towards us or going directly from us appears to stand still. In the case of the stars we can receive no assistance from change of size or of brightness. The stars show no true disks in our instruments, and the nearest of them is so far off that if it were approaching us at the rate of a hundred miles in a second of time, a whole century of such rapid approach would not do more than increase its brightness by the one-fortieth part.

Still it was only too clear that, so long as we were unable to ascertain directly those components of the stars' motions which lie in the line of sight, the speed and direction of the solar motion in space, and many of the great problems of the constitution of the heavens, must remain more or less imperfectly known. Now the spectroscope has placed in our hands this power, which, though so essential, appeared almost in the nature of things to lie for ever beyond our grasp; it enables us to measure directly, and under favourable circumstances to within a mile per second, or even less, the speed of approach or of recession of a heavenly body. This method of observation has the great advantage for the astronomer of being independent of the distance of the moving body, and is therefore as applicable and as certain in the case of a body on the extreme confines of the visible universe, so long as it is bright enough, as in the case of a neighbouring planet.

Doppler had suggested as far back as 1841 that the same principle, on which he had shown that a sound should become sharper or flatter if there were an approach or a recession between the ear and the source of the sound, would apply equally to light; and he went on to say that the difference of colour of some of the binary stars might be produced in this way by their motions. Doppler was right in that the principle is true in the case of light, but he was wrong in the particular conclusion which he drew from it. Even if we suppose a star to be moving with a sufficiently enormous velocity to alter sensibly its colour to the eye, no such change would actually be seen, for the reason that the store of invisible light beyond both limits of the visible spectrum, the blue and the red, would be drawn upon, and light-waves invisible to us would be exalted or degraded so as to take the place of those raised or lowered in the visible region, and the colour of the star would remain unchanged. About eight years later Fizeau pointed out the importance of considering the individual wave-lengths of which white light is composed. As soon, however, as we had learned to recognize the lines of known substances in the spectra of the heavenly bodies, Doppler's principle became applicable as the basis of a new and most fruitful method of investigation. The measurement of the small shift of the celestial lines from their true positions, as shown by the same lines in the spectrum of a terrestrial substance, gives to us the means of ascertaining directly in miles per second the speed of approach or of recession of the heavenly body from which the light has come.

An account of the first application of this method of research to the stars, which was made in my observatory in 1868, was given by Sir Gabriel Stokes from this chair at the meeting at Exeter in 1869. The stellar motions determined by me were shortly after confirmed by Prof. Vogel in the case of Sirius, and in the case of other stars by Mr. Christie, now Astronomer-Royal, at Greenwich; but, necessarily, in consequence of the inadequacy of the instruments then in use for so delicate an inquiry, the amounts of these motions were but approximate.

The method was shortly afterwards taken up systematically at Greenwich and at the Rugby Observatory. It is to be greatly regretted that, for some reasons, the results have not been sufficiently accordant and accurate for a research of such exceptional delicacy. On this account probably, as well as that the spectroscope at that early time had scarcely become a familiar instrument in the observatory, astronomers were slow in availing themselves of this new and remarkable power of investigation. That this comparative neglect of so truly wonderful a method of ascertaining what was otherwise outside our powers of observation has greatly retarded the progress of astronomy during the last fifteen years, is but too clearly shown by the brilliant results which within the last couple of years have followed fast upon the recent masterly application of this method by photography at Potsdam, and by eye with the needful accuracy at the Lick Observatory. At last this use of the spectroscope has taken its true place as one of the most potent methods of astronomical research. It gives us the motions of approach and of recession, not in angular measures, which depend for their translation into actual velocities upon separate determinations of parallactic displacements, but at once in terrestrial units of distance.

This method of work will doubtless be very prominent in the astronomy of the near future, and to it probably we shall have to look for the more important discoveries in sidereal astronomy which will be made during the coming century.

In his recent application of photography to this method of determining celestial motions, Prof. Vogel, assisted by Dr. Scheiner, considering the importance of obtaining the spectrum of as many stars as possible on an extended scale without an exposure inconveniently long, wisely determined to limit the part of the spectrum on the plate to the region for which the ordinary silver-bromide gelatine plates are most sensitive—namely, to a small distance on each side of G—and to employ as the line of comparison the hydrogen line near G, and recently also certain lines of iron. The most minute and complete mechanical arrangements were provided for the purpose of securing the absolute rigidity of the comparison spectrum relatively to that of the star, and for permitting temperature adjustments and other necessary ones to be made.

The perfection of these spectra is shown by the large number of lines, no fewer than 250 in the case of Capella, within the small region of the spectrum on the plate. Already the motions of about fifty stars have been measured with an accuracy, in the case of the larger number of them, of about an English mile per second.

At the Lick Observatory it has been shown that observations can be made directly by eye with an accuracy equally great. Mr. Keeler's brilliant success has followed in great measure from the use of the third and fourth spectra of a grating 14,438 lines to the inch. The marvellous accuracy attainable in his hands on a suitable star is shown by observations on three nights of the star Arcturus, the largest divergence of his measures being not greater than six tenths of a mile per second, while the mean of the three nights' work agreed with the mean of five photographic determinations of the same star at Potsdam to within one-tenth of an English mile. These are determinations of the motions of a sun so stupendously remote that even the method of parallax practically fails to fathom the depth of intervening space, and by means of light-waves which have been according to Elkin's nominal parallax, nearly 200 years upon their journey.

Mr. Keeler, with his magnificent means, has accomplished a task which I attempted in vain in 1874, with the comparatively poor appliances at my disposal, of measuring the motions in the line of sight of some of the planetary nebulæ. As the stars have considerable motions in space, it was to be expected that nebulæ should possess similar motions, for the stellar motions must have belonged to the nebulæ out of which they have been evolved. My instrumental means, limiting my power of detection to motions greater than twenty-five miles per second, were insufficient. Mr. Keeler has found in the examination of ten nebulæ motions varying from two miles to twenty-seven miles, with one exceptional motion of nearly forty miles.

For the nebula of Orion, Mr. Keeler finds a motion of recession of about ten miles a second. Now this motion agrees closely with what it should appear to have from the drift of the solar system itself, so far as it has been possible at present to ascertain the probable velocity of the sun in space. This grand nebula, of vast extent and of extreme tenuity, is probably more nearly at rest relatively to the stars of our system than any other celestial object we know; still it would seem more likely that even here we have some motion, small though it may be, than that the motions of the matter of which it is formed were so absolutely balanced as to leave this nebula in the unique position of absolute immobility in the midst of whirling and drifting suns and systems of suns.

The spectroscopic method of determining celestial motions in the line of sight has recently become fruitful in a new but not altogether unforeseen direction, for it has, so to speak, given us a separating power far beyond that of any telescope the glass-maker and the optician could construct, and so enabled us to penetrate into mysteries hidden in stars apparently single, and altogether unsuspected of being binary systems. The spectroscope has not simply added to the list of the known binary stars, but has given to us for the first time a knowledge of a new clas-

Digitized by Google

of stellar systems, in which the components are in some cases of nearly equal magnitude, and in close proximity, and are revolving with velocities greatly exceeding the planetary velocities of our system.

The K line in the photographs of Mizar, taken at the Harvard College Observatory, was found to be double at intervals of fifty-two days. The spectrum was therefore not due to a single source of light, but to the combined effect of two stars moving periodically in opposite directions in the line of sight. It is obvious that if two stars revolve round their common centre of gravity in a plane not perpendicular to the line of sight, all the lines in a spectrum common to the two stars will appear alternately single or double.

In the case of Mizar and the other stars to be mentioned, the spectroscopic observations are not as yet extended enough to furnish more than an approximate determination of the elements of their orbits.

Mizar especially, on account of its relatively long period—about 105 days—needs further observations. The two stars are moving each with a velocity of about fifty miles a second, probably in elliptical orbits, and are about 143 millions of miles apart. The stars, of about equal brightness, have together a mass about forty times as great as that of our sun.

A similar doubling of the lines showed itself in the Harvard photographs of β Aurigæ at the remarkably close interval of almost exactly two days, indicating a period of revolution of about four days. According to Vogel's later observations, each star has a velocity of nearly seventy miles a second, the distance between the stars being little more than seven and a half millions of miles, and the mass of the system 4·7 times that of the sun. The system is approaching us at the speed of about sixteen miles a second.

The telescope could never have revealed to us double stars of this order. In the case of β Aurigæ, combining Vogel's distance with Pritchard's recent determination of the star's parallax, the greatest angular separation of the stars as seen from the earth would be 1/200 part of a second of arc, and therefore very far too small for the highest powers of the largest telescopes. If we take the relation of aperture to separating power usually accepted, an object-glass of about 80 feet in diameter would be needed to resolve this binary star. The spectroscope, which takes no note of distance, magnifies, so to speak, this minute angular separation 4000 times; in other words, the doubling of the lines, which is the phenomenon that we have to observe, amounts to the easily measurable quantity of twenty seconds of arc.

There were known, indeed, variable stars of short period, which it had been suggested might be explained on the hypothesis of a dark body revolving about a bright sun in a few days, but this theory was met by the objection that no such systems of closely revolving suns were known to exist.

The Harvard photographs of which we have been speaking, were taken with a slitless form of spectroscope, the prisms being placed, as originally by Fraunhofer, before the object-glass of the telescope. This method, though it possesses some advantages, has the serious drawback of not permitting a direct comparison of the star's spectrum with terrestrial spectra. It is obviously unsuited to a variable star like Algol, where one star only is bright, for in such a case there would be no doubling of the lines, but only a small shift to and fro of the lines of the bright star as it moved in its orbit alternately towards and from our system, which would need for its detection the fiducial positions of terrestrial lines compared directly with them.

For such observations the Potsdam spectrograph was well adapted. Prof. Vogel found that the bright star of Algol did pulsate backwards and forwards in the visual direction in a period corresponding to the known variation of its light. The explanation which had been suggested for the star's variability, that it was partially eclipsed at regular intervals of 68·8 hours by a dark companion large enough to cut off nearly five-sixths of its light, was therefore the true one. The dark companion, no longer able to hide itself by its obscureness, was brought out into the light of direct observation by means of its gravitational effects.

Seventeen hours before minimum, Algol is receding at the rate of about 24½ miles a second, while seventeen hours after minimum it is found to be approaching with a speed of about 28½ miles. From these data, together with those of the variation of its light, Vogel found, on the assumption that both stars have the same density, that the companion, nearly as large as the sun, but with about one-fourth his mass, revolves with a velocity of about fifty-five miles a second. The bright star, of about twice the size and mass, moves about the common centre of gravity with the speed of about twenty-six miles a second. The system of the two stars, which are about 3¼ millions of miles apart, considered as a whole, is approaching us with a velocity of 2·4 miles a second. The great difference in luminosity of the two stars, not less than fifty times, suggests rather that they are in different stages of condensation, and dissimilar in density.

It is obvious that if the orbit of a star with an obscure companion is inclined to the line of sight, the companion will pass above or below the bright star, and produce no variation of its light. Such systems may be numerous in the heavens. In Vogel's photographs, Spica, which is not variable, by a small shifting of its lines reveals a backward and forward periodical pulsation due to orbital motion. As the pair whirl round their common centre of gravity, the bright star is sometimes advancing, at others receding. They revolve in about four days, each star moving with a velocity of about fifty-six miles a second in an orbit probably nearly circular, and possess a combined mass of rather more than two and a half times that of the sun. Taking the most probable value for the star's parallax, the greatest angular separation of the stars would be far too small to be detected with the most powerful telescopes.

If in a close double star the fainter companion is of the white-star type, while the bright star is solar in character, the composite spectrum would be solar with the hydrogen lines unusually strong. Such a spectrum would in itself afford some probability of a double origin, and suggest the existence of a companion star.

In the case of a true binary star the orbital motions of the pair would reveal themselves in a small periodical swaying of the hydrogen lines relatively to the solar ones.

Prof. Pickering considers that his photographs show ten stars with composite spectra; of these, five are known to be double. The others are: τ Persei, ζ Aurigæ, δ Sagittarii, 31 Ceti, and β Capricorni. Perhaps β Lyræ should be added to this list.

In his recent classical work on the rotation of the sun, Dunér has not only determined the solar rotation for the equator but for different parallels of latitude up to 75°. The close accordance of his results shows that these observations are sufficiently accurate to be discussed with the variation of the solar rotation for different latitudes which had been determined by the older astronomical methods from the observations of the solar spots.

Though I have already spoken incidentally of the invaluable aid which is furnished by photography in some of the applications of the spectroscope to the heavenly bodies, the new power which modern photography has put into the hands of the astronomer is so great, and has led already, within the last few years, to new acquisitions of knowledge of such vast importance, that it is fitting that a few sentences should be specially devoted to this subject.

Photography is no new discovery, being about half a century old; it may excite surprise, and indeed possibly suggest some apathy on the part of astronomers, that though the suggestion of the application of photography to the heavenly bodies dates from the memorable occasion when, in 1839, Arago, announcing to the Académie des Sciences the great discovery of Niepce and Daguerre, spoke of the possibility of taking pictures of the sun and moon by the new process, yet that it is only within a few years that notable advances in astronomical methods and discovery have been made by its aid.

The explanation is to be found in the comparative unsuitability of the earlier photographic methods for use in the observatory. In justice to the earlier workers in astronomical photography, among whom Bond, De la Rue, J. W. Draper, Rutherfurd, Gould, hold a foremost place, it is needful to state clearly that the recent great successes in astronomical photography are not due to greater skill, nor, to any great extent, to superior instruments, but to the very great advantages which the modern gelatine dry plate possesses for use in the observatory over the methods of Daguerre, and even over the wet collodion film on glass, which, though a great advance on the silver plate, went but a little way towards putting into the hands of the astronomer a photographic surface adapted fully to his wants.

The modern silver-bromide gelatine plate, except for its grained texture, meets the needs of the astronomer at all points. It possesses extreme sensitiveness; it is always ready for use;

Digitized by Google

it can be placed in any position; it can be exposed for hours; lastly, it does not need immediate development, and for this reason can be exposed again to the same object on succeeding nights, so as to make up by several instalments, as the weather may permit, the total time of exposure which is deemed necessary.

Without the assistance of photography, however greatly the resources of genius might overcome the optical and mechanical difficulties of constructing large telescopes, the astronomer would have to depend in the last resource upon his eye. Now we cannot by the force of continued looking bring into view an object too feebly luminous to be seen at the first and keenest moment of vision. But the feeblest light which falls upon the plate is not lost, but is taken in and stored up continuously. Each hour the plate gathers up 3600 times the light-energy which it received during the first second. It is by this power of accumulation that the photographic plate may be said to increase, almost without limit, though not in separating power, the optical means at the disposal of the astronomer for the discovery or the observation of faint objects.

Two principal directions may be pointed out in which photography is of great service to the astronomer. It enables him within the comparatively short time of a single exposure to secure permanently with great exactness the relative positions of hundreds or even of thousands of stars, or the minute features of nebulæ or other objects, or the phenomena of a passing eclipse, a task which by means of the eye and hand could only be accomplished, if done at all, after a very great expenditure of time and labour. Photography puts it in the power of the astronomer to accomplish in the short span of his own life, and so enter into their fruition, great works which otherwise must have been passed on by him as a heritage of labour to succeeding generations.

The second great service which photography renders is not simply an aid to the powers the astronomer already possesses. On the contrary, the plate, by recording light-waves which are both too small and too large to excite vision in the eye, brings him into a new region of knowledge, such as the infra-red and the ultra-violet parts of the spectrum, which must have remained for ever unknown but for artificial help.

The present year will be memorable in astronomical history for the practical beginning of the Photographic Chart and Catalogue of the Heavens, which took their origin in an International Conference which met in Paris in 1887, by the invitation of M. l'Amiral Mouchez, Director of the Paris Observatory.

The richness in stars down to the ninth magnitude of the photographs of the comet of 1882 taken at the Cape Observatory under the superintendence of Dr. Gill, and the remarkable star charts of the Brothers Henry which followed two years later, astonished the astronomical world. The great excellence of these photographs, which was due mainly to the superiority of the gelatine plate, suggested to these astronomers a complete map of the sky, and a little later gave birth in the minds of the Paris astronomers to the grand enterprise of an International Chart of the Heavens. The actual beginning of the work this year is in no small degree due to the great energy and tact with which the Director of the Paris Observatory has conducted the initial steps, through the many delicate and difficult questions which have unavoidably presented themselves in an undertaking which depends upon the harmonious working in common of many nationalities, and of no fewer than eighteen observatories in all parts of the world. The three years since 1887 have not been too long for the detailed organization of this work, which has called for several elaborate preliminary investigations on special points in which our knowledge was insufficient, and which have been ably carried out by Profs. Vogel and Bakhuyzen, Dr. Trépied, Dr. Scheiner, Dr. Gill, the Astronomer-Royal, and others. Time also was required for the construction of the new and special instruments.

The decisions of the Conference in their final form provide for the construction of a great photographic chart of the heavens with exposures corresponding to forty minutes' exposure at Paris, which it is expected will reach down to stars of about the fourteenth magnitude. As each plate is to be limited to four square degrees, and as each star, to avoid possible errors, is to appear on two plates, over 22,000 photographs will be required. For the more accurate determination of the positions of the stars, a *réseau* with lines at distances of 5 mm. apart is to be previously impressed by a faint light upon the plate, so that the image of the *réseau* will appear together with the images of the stars when the plate is developed. This great work will be divided, according to their latitudes, among eighteen observatories provided with similar instruments, though not necessarily constructed by the same maker. Those in the British dominions and at Tacubaya have been constructed by Sir Howard Grubb.

Besides the plates to form the great chart, a second set of plates for a catalogue is to be taken, with a shorter exposure, which will give stars to the eleventh magnitude only. These plates, by a recent decision of the Permanent Committee, are to be pushed on as actively as possible, though as far as may be practicable plates for the chart are to be taken concurrently. Photographing the plates for the catalogue is but the first step in this work, and only supplies the data for the elaborate measurements which have to be made, which are, however, less laborious than would be required for a similar catalogue without the aid of photography.

Already Dr. Gill has nearly brought to conclusion, with the assistance of Prof. Kapteyn, a preliminary photographic survey of the southern heavens.

With an exposure sufficiently long for the faintest stars to impress themselves upon the plate, the accumulating action still goes on for the brighter stars, producing a great enlargement of their images from optical and photographic causes. The question has occupied the attention of many astronomers, whether it is possible to find a law connecting the diameters of these more or less over-exposed images with the relative brightness of the stars themselves. The answer will come out undoubtedly in the affirmative, though at present the empirical formulæ which have been suggested for this purpose differ from each other. Captain Abney proposes to measure the total photographic action, including density as well as size, by the obstruction which the stellar image offers to light.

A further question follows as to the relation which the photographic magnitudes of stars bear to those determined by eye. Visual magnitudes are the physiological expression of the eye's integration of that part of the star's light which extends from the red to the blue. Photographic magnitudes represent the plate's integration of another part of the star's light—namely, from a little below where the power of the eye leaves off in the blue to where the light is cut off by the glass, or is greatly reduced by want of proper corrections when a refracting telescope is used. It is obvious that the two records are taken by different methods in dissimilar units of different parts of the star's light. In the case of certain coloured stars the photographic brightness is very different from the visual brightness; but in all stars, changes, especially of a temporary character, may occur in the photographic or the visual region, unaccompanied by a similar change in the other part of the spectrum. For these reasons it would seem desirable that the two sets of magnitudes should be tabulated independently, and be regarded as supplementary of each other.

The determination of the distances of the fixed stars from the small apparent shift of their positions when viewed from widely separated positions of the earth in its orbit is one of the most refined operations of the observatory. The great precision with which this minute angular quantity—a fraction of a second only—has to be measured, is so delicate an operation with the ordinary micrometer, though, indeed, it was with this instrument that the classical observations of Sir Robert Ball were made, that a special instrument, in which the measures are made by moving the two halves of a divided object-glass, known as a heliometer, has been pressed into this service, and quite recently, in the skilful hands of Dr. Gill and Dr. Elkin, has largely increased our knowledge in this direction.

It is obvious that photography might be here of great service, if we could rely upon measurements of photographs of the same stars taken at suitable intervals of time. Prof Pritchard, to whom is due the honour of having opened this new path, aided by his assistants, has proved by elaborate investigations that measures for parallax may be safely made upon photographic plates, with, of course, the advantages of leisure and repetition; and he has already by this method determined the parallax for twenty-one stars with an accuracy not inferior to that of values previously obtained by purely astronomical methods.

The remarkable successes of astronomical photography, which depend upon the plate's power of accumulation of a very feeble light acting continuously through an exposure of several hours, are worthy to be regarded as a new revelation. The first chapter

Digitized by Google

opened when, in 1880, Dr. Henry Draper obtained a picture of the nebula of Orion; but a more important advance was made in 1883, when Dr. Common, by his photographs, brought to our knowledge details and extensions of this nebula hitherto unknown. A further disclosure took place in 1885, when the Brothers Henry showed for the first time in great detail the spiral nebulosity issuing from the bright star Maia of the Pleiades, and, shortly afterwards, nebulous streams about the other stars of this group. In 1886, Mr. Roberts, by means of a photograph to which three hours' exposure had been given, showed the whole background of this group to be nebulous. In the following year Mr. Roberts more than doubled for us the great extension of the nebular region which surrounds the trapezium in the constellation of Orion. By his photographs of the great nebula in Andromeda he has shown the true significance of the dark canals which had been seen by the eye. They are in reality spaces between successive rings of bright matter, which appeared nearly straight owing to the inclination in which they lie relatively to us. These bright rings surround an undefined central luminous mass. I have already spoken of this photograph.

Some recent photographs by Mr. Russell show that the great rift in the Milky Way in Argus, which to the eye is void of stars, is in reality uniformly covered with them. Also, quite recently, Mr. George Hale has photographed the prominences by means of a grating, making use of the lines H and K.

The heavens are richly but very irregularly inwrought with stars, the brighter stars cluster into well known groups upon a background formed of an enlacement of streams and convoluted windings and intertwined spirals of fainter stars, which becomes richer and more intricate in the irregularly rifted zone of the Milky Way.

We, who form part of the emblazonry, can only see the design distorted and confused; here crowded, there scattered, at another place superposed. The groupings due to our position are mixed up with those which are real.

Can we suppose that each luminous point has no relation to the others near it than the accidental neighbourship of grains of sand upon the shore, or of particles of the wind-blown dust of the desert? Surely every star, from Sirius and Vega down to each grain of the light-dust of the Milky Way, has its present place in the heavenly pattern from the slow evolving of its past. We see a system of systems, for the broad features of clusters and streams and spiral windings which mark the general design are reproduced in every part. The whole is in motion, each point shifting its position by miles every second, though from the august magnitude of their distances from us and from each other, it is only by the accumulated movements of years or of generations that some small changes of relative position reveal themselves.

The deciphering of this wonderfully intricate constitution of the heavens will be undoubtedly one of the chief astronomical works of the coming century. The primary task of the sun's motion in space, together with the motions of the brighter stars, has been already put well within our reach by the spectroscopic method of the measurement of star-motions in the line of sight.

From other directions information is accumulating: from photographs of clusters and parts of the Milky Way, by Roberts in this country, Barnard at the Lick Observatory, and Russell at Sydney; from the counting of stars, and the detection of their configurations, by Holden and by Backhouse; from the mapping of the Milky Way by eye, at Parsonstown; from photographs of the spectra of stars, by Pickering at Harvard and in Peru; and from the exact portraiture of the heavens in the great international star chart which begins this year.

I have but touched some only of the problems of the newer side of astronomy. There are many others which would claim our attention if time permitted. The researches of the Earl of Rosse on lunar radiation, and the work on the same subject and on the sun, by Langley. Observations of lunar heat with an instrument of his own invention by Mr. Boys; and observations of the variation of the moon's heat with its phase by Mr. Frank Very. The discovery of the ultra-violet part of the hydrogen spectrum, not in the laboratory, but from the stars. The confirmation of this spectrum by terrestrial hydrogen in part by H. W. Vogel, and in its all but complete form by Cornu, who found similar series in the ultra-violet spectra of aluminium and thallium. The discovery of a simple formula for the hydrogen series by Balmer. The important question as to the numerical spectral relationship of different substances, especially in connection with their chemical properties; and the further question as to the origin of the harmonic and other relations between the lines and the groupings of lines of spectra; on these points contributions during the past year have been made by Rudolf v. Kövesligethy, Ames, Hartley, Deslandres, Rydberg, Grünwald, Kayser and Runge, Johnstone Stoney, and others. The remarkable employment of interference phenomena by Prof. Michelson for the determination of the size, and distribution of light within them, of the images of objects which when viewed in a telescope subtend an angle less than that subtended by the light-wave at a distance equal to the diameter of the objective. A method applicable not alone to celestial objects, but also to spectral lines, and other questions of molecular physics.

Along the older lines there has not been less activity; by newer methods, by the aid of larger or more accurately constructed instruments, by greater refinement of analysis, knowledge has been increased, especially in precision and minute exactness.

Astronomy, the oldest of the sciences, has more than renewed her youth. At no time in the past has she been so bright with unbounded aspirations and hopes. Never were her temples so numerous, nor the crowd of her votaries so great. The British Astronomical Association formed within the year numbers already about 600 members. Happy is the lot of those who are still on the eastern side of life's meridian!

Already, alas! the original founders of the newer methods are falling out—Kirchhoff, Ångström, D'Arrest, Secchi, Draper, Becquerel; but their places are more than filled; the pace of the race is gaining, but the goal is not and never will be in sight.

Since the time of Newton our knowledge of the phenomena of Nature has wonderfully increased, but man asks, perhaps more earnestly now than in his days, What is the ultimate reality behind the reality of the perceptions? Are they only the pebbles of the beach with which we have been playing? Does not the ocean of ultimate reality and truth lie beyond?

SECTION A.

MATHEMATICS AND PHYSICS.

OPENING ADDRESS BY PROF. OLIVER J. LODGE, D.Sc., LL.D., F.R.S., PRESIDENT OF THE SECTION.

DURING the past year three or four events call for special mention in an annual deliverance of this kind by a physicist.

One is the Faraday centenary, which was kept in a happy and simple manner by a cosmopolitan gathering in the place so long associated with his work, and by discourses calling attention to the modern development of discoveries made by him.

Another is the decease of the veteran Wilhelm Weber, one of the originators of that absolute system of measurement which, though still ungrasped in its simplicity and completeness by the majority of men engaged in practice, nor even, I fear, wholly understood by some of those engaged in University teaching, has yet done so much, and is destined to do still more, for the unification of physical science, and for a thorough comprehension of its range and its limitations.

A third event of importance during the year is the discovery in America of a binary system of stars, revolving round each other with grotesque haste, and with a proximity to each other such as to render their ordinary optical separation quite impossible. Ideas concerning the future of such systems, if, as seems probable, their revolution period is shorter than their axial period, will readily suggest themselves, in accordance with the principles elaborated by Prof. George Darwin. The subject more properly belongs to our President, but I may parenthetically exclaim at the singular absurdity of the notion which was once propounded by a philosopher, that motion of stars in our line of sight must for ever remain unknown to us; when the mere time of revolution of a satellite, compared with its distance from its central body, is theoretically sufficient to give us information on this head. As a matter of pedagogy it is convenient to observe that the principle called Doppler's, which is generally known to apply to the periodic disturbances called Light and Sound, applies equally to all periodic occurrences; and that the explanation of anomalies of Jupiter's first satellite by Roemer may be regarded as an instance of Doppler's

Digitized by Google

principle.[1] Any discrepancy between the observed and the calculated times of revolution of stars round each other can possibly be explained by a relative motion between us and the pair of bodies along the line of sight.

If our text-books clearly recognized this, we should not so often find examination candidates asserting that the apparent time of revolution of a satellite of Jupiter depends on the distance of the earth from that planet, instead of on the speed. I should indeed be sorry to be judged by the performance of my own students, but I fear that many of the less obvious mistakes made by reasonably trained examination candidates are more directly traceable to their teachers than some of us as teachers would like to admit.

The change in the refrangibility of light by reason of the motion of its source, though commonplace enough now, was at first regarded as too small to be observed, and one or two attempts directed to detecting the effect of this principle on the spectra of the stars, or sometimes on sunlight reflected by a 45° mirror into the line of the earth's motion (which is not a possible method), wholly failed. I take pleasure in remembering that this effect was clearly observed for the first time by the gentleman we this year honour as our President; and that it is by this very means that the latest sensational discovery in astronomy of the rapidly revolving twin star β-Aurigæ, by Prof. Pickering and the staff connected with the Draper Memorial, was made.

The funds for the investigation that led to this result were provided by Mrs. Draper, as a memorial to her late husband; and if β-Aurigæ does not constitute a satisfactory memorial, I am at a loss to conceive the kind of tombstone which the relations of a man of science would prefer.

The fourth event to which it behoves me to refer is the practical discovery of a physical method for colour photography. When I say practical I do not mean commercial, nor do I know that it will ever become applicable to the ordinary business of the photographer. Whether it does or not, it is a sound achievement by physical means of a result which the chemical means hitherto tried failed, some think necessarily failed, to produce. I say practical, because already it had been suggested as possible theoretically; and a step toward it, indeed very near it, had been actually made. The first suggestion of the method, so far as I know, was made by Lord Rayleigh in the course of a mathematical paper on the reflection of light, and with reference to some results of Becquerel obtained on a totally different plan. He said in a note that if by normal reflection waves of light were converted into stationary waves, they could shake out silver in strata half a wave-length apart, and that such strata would give selective reflection and show iridescence.

The colour of certain crystals of chlorate of potash, described in a precise manner by Sir George Stokes (Proc. Roy. Soc., February 1885), and also the colours of opal and ancient glass, had been elaborately and completely explained by Lord Rayleigh on this theory of a periodic structure (the laminated structure in the case of chlorate of potash being caused by twinning) (Phil. Mag., September 1888, pp. 256 and 241); and he subsequently illustrated it with sound and a series of muslin disks one behind the other on a set of lazy-tongs. Each membrane reflected an inappreciable amount, but successive equidistant membranes reinforced each other's action, and the entire set reflected distinctly one definite note, of wave-length twice the distance between adjacent muslins. So also with any series of equidistant strata each very slightly reflecting. They should give selective reflection, and the spectrum of their reflected beam should show a single line or narrow band, corresponding to a wave-length twice the distance of the strata apart.[2]

[1] Dr. Huggins has just pointed out to me a perfectly clear statement to the above effect in Professor Tait's little book on Light.

[2] The footnote of Lord Rayleigh on page 158, *Phil. Mag.*, 1887, vol. xxiv., is brief and forcible enough to quote in full:—"A detailed experimental examination of the various cases in which a laminated structure leads to a powerful but highly selected reflection would be of value. The most frequent examples are met with in the organic world. It has occurred to me that Becquerel's reproduction of the spectrum in natural colours upon silver plates may perhaps be explicable in this manner. The various parts of the film of subchloride of silver with which the metal is coated may be conceived to be subjected during exposure to *stationary* luminous waves of nearly definite wave-length, the effect of which might be to impress upon the substance a periodic structure occurring at intervals equal to *half* the wave-length of light; just as a sensitive flame exposed to stationary sonorous waves is influenced at the loops, but not at the nodes (*Phil. Mag.*, March 1879, p. 153). In this way the operation of any kind of light would be to produce just such a modification of the film as would cause it to reflect copiously that particular kind of light. I abstain at present from developing this suggestion, in the hope of soon finding an opportunity of making myself experimentally acquainted with the subject."

Independently of all this, Herr Otto Wiener, imitating Hertz's experiments with ordinary light, in 1889 reflected a beam directly back on itself, and, by interposing a very thin collodion film at extraordinarily oblique incidence, succeeded in the difficult experiment of so magnifying by the cosine of inclination the half wave-length, as to get the silver deposited in strata of visible width, and thus to photograph the interference nodes themselves at the places where they were cut by the plane of the film (*Wiedemann's Annalen*, vol. xl., 1890).

Then M. Lippmann, using a thicker film, not put obliquely but normal to the light, obtained the strata within the thickness of the film itself—hundreds of layers; and so, employing incidence light of definite wave-length, was able to produce a stratified deposit, which reflected back at appropriate incidences the same wave-length as produced it; thus reproducing, of course, the definite colour.

It is probable that the silver is first shaken out at the ventral segments, but that the strata so formed are thick and blurry. I conjecture that by over-exposure this deposit is nearly all mopped up again, traces being left only at the nodes, where the action is very feeble and takes a long time to occur; but that these residual strata, being fairly sharp and definite, will be likely to give much better effects. And so I suppose that these are what are actually effective in obtaining M. Lippmann's very interesting, though not yet practically useful, result.

I now leave the retrospect of what has been done, although many other topics might usefully detain us, and I proceed to glance forward at the progress ahead and at the means we have for effectively grappling with our due share of it.

There is a subject which has long been in my mind, and which I determined to bring forward whenever I had a cathedral opportunity of doing so; and now, if ever, is a suitable occasion. It is to call attention to the fact that the further progress of physical science in the somewhat haphazard and amateur fashion in which it has been hitherto pursued in this country is becoming increasingly difficult, and that the quantitative portion especially should be undertaken in a permanent and publicly-supported physical laboratory on a large scale. If such an establishment were to weaken the sinews of private enterprise and individual research it should be strenuously opposed; but, in my opinion, it would have the opposite effect, by relieving the private worker of much which he can only with great difficulty, sacrifice, and expense, undertake. To illustrate more precisely what I mean, it is sufficient to recall the case of astronomy. The amateur astronomer has much work lying ready to his hand, and he grapples with it manfully. To him is left the striking out of new lines and the guerilla warfare of science. Skirmishing and brilliant cavalry evolutions are his natural field, he should not be called upon to take part in the general infantry advance. It is wasting his energies, and he could not do it in the long run well. What, for instance, would have been the state of astronometry—the nautical almanac department of astronomy—without the consecutive and systematic work of the National Observatory at Greenwich? It may be that some enthusiastic amateurs would have devoted their lives to this routine kind of work, and here at one time and there at another a series of accurate observations would have been kept for several years. Pursued in that way, however, not only would the effort be spasmodic and temporary, but the energy and enthusiasm of those amateurs would have been diverted from the pioneering more suited to them, and have been cramped in the groove of routine, eminently adapted to a permanent official staff, but not wholesome for an individual.

Long-continued consecutive observations may be made by a leader of science, as functions may be tabulated by an eminent mathematician; but if the work can be done almost equally well (some would say better) by a professional observer or computator, how great an economy results.

Now all this applies equally to physics. The ohm has been determined with 4-figure, perhaps with 5-figure, accuracy; but think of the list of eminent men to whose severe personal labour we owe this result, and ask if the spoil is worth the cost. Perhaps in this case it is, as a specimen of a well-conducted determination. We must have a few specimens, and our leaders must show us the way to do things. But let us not continue to use them for such purposes much longer. The quest of the fifth or sixth decimal is a very legitimate, and may become a very absorbing, quest, but there are plenty of the rank and file who can undertake it if properly generalled and led: not as isolated individuals, but as workers in a National Laboratory under a competent head and a governing committee. By this means work far

Digitized by Google

greater in quantity, and in the long run more exact in quality, can be turned out, by patient and conscientious labour without much genius, by the gradual improvement of instrumental means, by the skill acquired by practice, and by the steady drudgery of routine. Paris has long had one form of such an institution, in the Conservatoire des Arts et Métiers, and has been able to impose the metric system on the civilised world in consequence. It can also point to the classical determinations of Regnault as the fruits of just such a system. Berlin is now starting a similar or a more ambitious scheme for a permanent national physical institute. Is it not time that England, who in physical science, I venture to think, may in some sort claim a leading place, should be thinking of starting the same movement?

The Meteorological and Magnetic Observatory at Kew (in the inauguration of which this Association took so large a part) is a step, and much useful quantitative work is done there. The new Electric Standardizing Laboratory of the Board of Trade is another and, in some respects perhaps, a still closer appproximation to the kind of thing I advocate. But what I want to see is a much larger establishment erected on the most suitable site, limited by no speciality of aim nor by the demands of the commercial world, furnished with all appropriate appliances, to be amended and added to as time goes on and experience grows, and invested with all the dignity and permanence of a national institution: a Physical Observatory, in fact, precisely comparable to the Greenwich Observatory, and aiming at the very highest quantitative work in all departments of physical science. That the arts would be benefited may be assumed without proof. It is largely the necessity of engineers that has inspired the amount of accuracy in electrical matters already attained. The work and appliances of the mechanical engineer eclipse the present achievements of the physicist in point of accuracy, and it is by the aid of the mechanician and optician that precision even in astronomy has reached so high a stage. There is no reason why physical determinations should be conducted in an amateur fashion, with comparatively imperfect instruments, as at present they mostly are. Discoveries lie along the path of extreme accuracy, and they will turn up in the most unexpected way. The aberration of light would not have been discovered had not Bradley been able to measure to less than 1 part in 10,000; and what a brilliant and momentous discovery it was! He was aiming at the detection of stellar parallax, but the finite velocity of light was a bigger discovery than any parallax. This is the type of result which sometimes lurks in the fifth decimal, and which confers upon it an importance beside which the demands of men who wish to serve the taste and the pocket of the British public sink into insignificance.

In a National Observatory accuracy should be the one great end: the utmost accuracy in every determination that is decided on and made. Only one thing should be more thought of than the fifth significant figure, and that is the sixth. The consequences flowing from the results may safely be left; such as are not obvious at once will distil themselves out in time. And the great army of outside physicists, assured of the good work being done at headquarters, will (to speak again in astronomical parable) cease from peddling with taking transits or altitudes, and will be free to discover comets, to invent the spectroscope, to watch solar phenomena, to chemically analyse the stars, to devise celestial photography, and to elaborate still more celestial theories; all of which novelties in their maturity may be handed over to the National Observatory, to be henceforth incorporated with, and made part of, its routine life; leaving the advance guard and skirmishers free to explore fresh territory, secure in the knowledge that what they have acquired will be properly surveyed, mapped, and utilised, without further attention from them. As to the practical applications, they may in any case be left to take care of themselves. The instinct of humanity in this direction, and the so-called solid gains associated with practical achievements, will always secure a sufficient number of acute and energetic workers to turn the new territory into arable land and pasture adapted to the demands of the average man. The labour of the agriculturist in rendering soil fertile is, of course, beyond praise; but it is not the work of the pioneer. As Mr. Huxley eloquently put it, when contrasting the application of science with the advance of science itself, speaking of the things of commercial value which the physical philosopher sometimes discovers:—"Great is the rejoicing of those who are benefited thereby, and, for the moment, science is the Diana of all the craftsmen. But even while the cries of jubilation resound, and this flotsam and jetsam of the tide of investigation is being turned into the wages of workmen and the wealth of capitalists, the crest of the wave of scientific investigation is far away on its course over the illimitable ocean of the unknown."

I have spoken of the work of the National Laboratory as devoted to accuracy. It is hardly necessary to say that it will be also the natural custodian of our standards, in a state fit for use and for comparison with copies sent to be certified. Else perhaps some day our standard ohm may be buried in a brick wall at Westminster, and no one living may be able to recall precisely where it is.

But, in addition to these main functions, there is another, equally important with them, to which I must briefly refer. There are many experiments which cannot possibly be conducted by an individual, because forty or fifty years is not long enough for them. Secular experiments on the properties of materials—the elasticity of metals, for instance; the effect of time on molecular arrangement; the influence of long exposure to light, or to heat, or to mechanical vibration, or to other physical agents.

Does the permeability of soft iron decay with age, by reason of the gradual cessation of its Ampèrian currents? Do gases cool themselves when adiabatically preserved, by reason of imperfect elasticity or too many degrees of freedom of their molecules? Unlikely, but not impossible. Do thermo-electric properties alter with time? And a multitude of other experiments which appear specially applicable to substances in the solid state—a state which is more complicated, and has been less investigated, than either the liquid or the gaseous: a state in which time and past history play an important part.

Whichever of these long researches requires to be entered on, a national laboratory, with permanent traditions and a continuous life, is undoubtedly the only appropriate place. At such a place as Glasgow the exceptional magnitude of a present occupant may indeed inspire sufficient piety in a successor to secure the continuance of what has been there begun; but in most college laboratories, under conditions of migration, interregnum, and a new *régime*, continuity of investigation is hopeless.

I have at any rate said enough to indicate the kind of work for which the establishment of a well-furnished laboratory with fully equipped staff is desirable, and I do not think that we, as a nation, shall be taking our proper share of the highest scientific work of the world until such an institution is started on its career.

There is only one evil which, so far as I can see, is to be feared from it: if ever it were allowed to impose on outside workers as a central authority, from which infallible dicta were issued, it would be an evil so great that no amount of good work carried on by it could be pleaded as sufficient mitigation.

If ever by evil chance such an attitude were attempted, it must rest with the workers of the future to see that they permit no such shackles; for if they are not competent to be independent, and to contemn the voice of authority speaking as mere authority, if their only safeguard lies in the absence of necessity for struggle and effort, they cannot long hope to escape from the futility which surely awaits them in other directions.

I am thus led to take a wider range, and, leaving temporary and special considerations, to speak of a topic which is as yet beyond the pale of scientific orthodoxy, and which I might, more wisely, leave lying by the roadside. I will, however, take the risk of introducing a rather ill-favoured and disreputable looking stranger to your consideration, in the belief—I might say, in the assured conviction—that he is not all scamp, and that his present condition is as much due to our long-continued neglect as to any inherent incapacity for improvement in the subject.

I wish, however, strenuously to guard against its being supposed that this Association, in its corporate capacity, lends its countenance to, or looks with any favour on, the outcast. What I have to say—and after all, it will not be much—must rest on my own responsibility. I should be very sorry for any adventitious weight to attach to my observations on forbidden topics from the accident of their being delivered from this chair. The objection at which I have now hinted is the only one that seems to me to have any just weight, and on all other counts I am willing to incur such amount of opprobrium as naturally attaches to those who enter on a region where the fires of controversy are not extinct, and in which it is quite impossible, as well as undesirable, for everyone to think alike.

It is but a platitude to say that our clear and conscious aim should always be truth, and that no lower or meaner standard

Digitized by Google

should ever be allowed to obtrude itself before us. Our ancestors fought hard and suffered much for the privilege of free and open inquiry, for the right of conducting investigation untrammelled by prejudice and foregone conclusions, and they were ready to examine into any phenomenon which presented itself. This attitude of mind is perhaps necessarily less prominent now, when so much knowledge has been gained, and when the labours of many individuals may be rightly directed entirely to its systematization and a study of its inner ramifications; but it would be a great pity if a too absorbed attention to what has already been acquired, and to the fringe of territory lying immediately adjacent thereto, were to end in our losing the power of raising our eyes and receiving evidence of a totally fresh kind, of perceiving the existence of regions into which the same processes of inquiry as had proved so fruitful might be extended, with results at present incalculable and perhaps wholly unexpected. I myself think that the ordinary processes of observation and experiment are establishing the existence of such a region; that, in fact, they have already established the truth of some phenomena not at present contemplated by science, and to which the orthodox man shuts his ears.

For instance, there is the question whether it has or has not been established by direct experiment that a method of communication exists between mind and mind irrespective of the ordinary channels of consciousness and the known organs of sense, and, if so, what is the process. It can hardly be through some unknown sense organ, but it may be by some direct physical influence on the ether, or it may be in some still more subtle manner. Of the process I as yet know nothing. For brevity it may be styled "thought-transference," though the name may turn out to be an unsuitable one after further investigation. Further investigation is just what is wanted. No one can expect others to accept his word for an entirely new fact, except as establishing a *prima facie* case for investigation.

But I am only now taking this as an instance of what I mean; whether it be a truth or a fiction, there is not, I suppose, one of the recognized scientific societies who would receive a paper on the subject.[1] There are individual scientific men who have investigated these matters for themselves; there are others who are willing to receive evidence, who hold their minds open and their judgment in suspense; but these are only individuals. The great majority, I think I am right in saying, feel active hostility to these researches and a determined opposition to the reception or discussion of evidence. And they feel this confirmed scepticism, as they call it, not after prolonged investigation, for then it might be justified, but sometimes after no investigation at all. A few tricks at a public performance, or the artifices of some impostor, and they decline to consider the matter further.

That individuals should take this line is, however, natural enough; they may be otherwise occupied and interested. Everybody is by no means bound to investigate everything; though, indeed, it is customary in most fields of knowledge for those who have kept aloof from a particular inquiry to defer in moderation to those who have conducted it, without feeling themselves called upon to express an opinion. Some there are, no doubt, who consider that they have given sufficient time and attention to the subject with only negative results. Their evidence is, of course, important; but plainly, negative evidence should be of immense bulk and weight before it can outweigh even a moderate amount of positive evidence. However, it is not of the action of individuals that I wish to speak, it is of the attitude to be adopted by scientific bodies in their corporate capacity; and for a corporate body of men of science, inheritors of the hard-won tradition of free and fearless inquiry into the facts of nature untrammelled by prejudice, for any such body to decline to receive evidence laboriously attained and discreetly and inoffensively presented by observers of accepted competency in other branches, would be, if ever actually done and persisted in, a terrible throwing away of their prerogative, and an imitation of the errors of a school of thought against which the struggle was at one time severe.

In the early days of the Copernican theory, Galileo for some years refrained from teaching it, though fully believing its truth, because he considered that he had better get more fully settled in his University chair before evoking the storm of controversy which the abandonment of the Ptolemaic system would arouse. The same thing in very minor degree is going on to-day. I know of men who hesitate to avow interest in these new investigations (I do not mean credence—the time is too early for avowing credence in any but the most rudimentary and definitely ascertained facts—but hesitate to avow interest) until they have settled down more securely and made a name for themselves in other lines. Caution and slow progress are extremely necessary; fear of avowing interest or of examining into unorthodox facts is, I venture to say, not in accordance with the highest traditions of the scientific attitude.

We are, I suppose, to some extent afraid of each other, but we are still more afraid of ourselves. We have great respect for the opinions of our elders and superiors; we find the matter distasteful to them, so we are silent. We have, moreover, a righteous mistrust of our own powers and knowledge; we perceive that it is a wide region extending into several already cultivated branches of science, that a many-sided and highly-trained mind is necessary adequately to cope with all its ramifications, that in the absence of strict inquiry imposture has been rampant in some portions of it for centuries, and that unless we are preternaturally careful we may get led into quagmires if we venture on it at all.

Now let me be more definite, and try to state what this field is, the exploration of which is regarded as so dangerous. I might call it the borderland of physics and psychology. I might call it the connection between life and energy; or the connection between mind and matter. It is an intermediate region, bounded on the north by psychology, on the south by physics, on the east by physiology, and on the west by pathology and medicine. An occasional psychologist has groped down into it and become a metaphysician. An occasional physicist has wandered up into it and lost his base, to the horror of his quondam brethren. Biologists mostly look at it askance, or deny its existence. A few medical practitioners, after long maintenance of a similar attitude, have begun to annex a portion of its western frontier. The whole region seems to be inhabited mainly by savages, many of them, so far as we can judge from a distance, given to gross superstition. It may, for all I know, have been hastily traversed, and rudely surveyed by a few clear-eyed travellers; but their legends concerning it are not very credible, certainly are not believed.

Why not leave it to the metaphysicians? I say it has been left to them long enough. They have explored it with insufficient equipment. The physical knowledge of the great philosophers has been necessarily scanty. Men of genius they were, and their writings may, when interpreted, mean much. But to us, as physicists, they are unsatisfactory; their methods are not our methods. They may be said to have floated a balloon over the region with a looking-glass attached, in which they have caught queer and fragmentary glimpses. They may have seen more than we give them credit for, but they appear to have guessed far more than they saw.

Our method is different. We prefer to creep slowly from our base of physical knowledge, to engineer carefully as we go, establishing forts, making roads, and thoroughly exploring the country; making a progress very slow, but very lasting. The psychologists from their side may meet us. I hope they will; but one or other of us ought to begin.

A vulnerable spot on our side seems to be the connection between life and energy. The conservation of energy has been so long established as to have become a commonplace. The relation of life to energy is not understood. Life is not energy, and the death of an animal affects the amount of energy no whit; yet a live animal exerts control over energy which a dead one cannot. Life is a guiding or directing principle, disturbing to the physical world but not yet given a place in the scheme of physics. The transfer of energy is accounted for by the performance of work; the guidance of energy needs no work, but demands force only. What is force? and how can living beings exert it in the way they do? An automaton worked by preceding conditions—that is, by the past—say the materialists. Are we so sure that they are not worked by the future too? In other words, that the totality of things, by which every one must admit that actions are guided, includes the future as well as the past, and that to attempt to deduce those actions from the past only will prove impossible.[1] In some way matter can be moved, guided, disturbed, by the agency of living beings; in some way there is a control, a directing-agency active, and events are caused at its choice and will that would not otherwise happen.

[1] This, however, is mere conjecture. I am not aware that the experiment has been tried.

[1] The expression "controlled by the future" I first heard in a conversation with G. F. Fitzgerald, who seemed to consider it applicable to all events, without exception.

Digitized by Google

A luminous and helpful idea is that *time* is but a relative mode of regarding things; we progress through phenomena at a certain definite pace, and this subjective advance we interpret in an objective manner, as if events necessarily happened in this order and at this precise rate. But that may be only one mode of regarding them. The events may be in some sense existent always, both past and future, and it may be we who are arriving at them, not they which are happening. The analogy of a traveller in a railway train is useful. If he could never leave the train nor alter its pace, he would probably consider the landscapes as necessarily successive, and be unable to conceive their co-existence.

The analogy of a solid cut into sections is closer. We recognise the universe in sections, and each section we call the present. It is like the string of slices cut by a microtome; it is our way of studying the whole. But we may err in supposing that the body only exists in the slices which pass before our microscope in regular order and succession.

We perceive, therefore, a possible fourth-dimensional aspect about time, the inexorableness of whose flow may be a natural part of our present limitations. And if once we grasp the idea that past and future may be actually existing, we can recognise that they may have a controlling influence on all present action, and the two together may constitute "the higher plane," or the totality of things, after which, as it seems to me, we are impelled to seek, in connection with the directing of force or determinism, and the action of living beings consciously directed to a definite and preconceived end.

Inanimate matter is controlled by the *vis a tergo;* it is operated on solely by the past.[1] Given certain conditions, and the effect in due time follows. Attempts have been made to apply the same principle to living and conscious beings, but without much success. These seem to work for an object, even if it be the mere seeking for food; they are controlled by the idea of something not yet palpable. Given certain conditions, and their action cannot certainly be predicted; they have a sense of option and free will. Either their actions are really arbitrary and indeterminate—which is highly improbable—or they are controlled by the future as well as by the past. Imagine beings thus controlled: automata you may still call them, but they will be living automata, and will exhibit all the characteristics of live creatures. Moreover, if they have a merely experiential *knowledge*, necessarily limited by memory and bounded by the past, they will be unable to predict each other's actions with any certainty, because the whole of the data are not before them. May not a clearer apprehension of the meaning of life and will and determinism be gradually reached in some such direction as this?

By what means is force exerted, and what, definitely, is force? I can hardly put the question here and now so as to be intelligible, except to those who have approached and thought over the same difficulties; but I venture to say that there is here something not provided for in the orthodox scheme of physics; that modern physics is not complete, and that a line of possible advance lies in this direction.

I might go further. Given that force can be exerted by an act of will, do we understand the mechanism by which this is done? And if there is a gap in our knowledge between the conscious idea of a motion and the liberation of muscular energy needed to accomplish it, how do we know that a body may not be moved without ordinary material contact by an act of will? I have no evidence that such a thing is possible. I have tried once or twice to observe its asserted occurrence, and failed to get anything that satisfied me. Others may have been more fortunate. In any case, I hold that we require more knowledge before we can deny the possibility. If the conservation of energy were upset by the process, we should have grounds for denying it; but nothing that we know is upset by the discovery of a novel medium of communication, perhaps some more immediate action through the ether. It is no use theorising; it is unwise to decline to examine phenomena because we feel too sure of their impossibility. We ought to know the universe very thoroughly and completely before we take up that attitude.

Again, it is familiar that a thought may be excited in the brain of another person, transferred thither from our brain, by pulling a suitable trigger; by liberating energy in the form of sound, for instance, or by the mechanical act of writing, or in other ways. A prearranged code called language, and a material medium of communication, are the recognised methods. May there not also be an immaterial (perhaps an ethereal) medium of communication? Is it possible that an idea can be transferred from one person to another by a process such as we have not yet grown accustomed to, and know practically nothing about? In this case I have evidence. I assert that I have seen it done; and am perfectly convinced of the fact. Many others are satisfied of the truth of it too. Why must we speak of it with bated breath, as of a thing of which we are ashamed? What right have we to be ashamed of a truth?

And after all, when we have grown accustomed to it, it will not seem altogether strange. It is, perhaps, a natural consequence of the community of life or family relationship running through all living beings. The transmission of life may be likened in some ways to the transmission of magnetism, and all magnets are sympathetically connected, so that if suitably suspended a vibration from one disturbs others, even though they be distant ninety-two million miles.

It is sometimes objected that, granting thought-transference or telepathy to be a fact, it belongs more especially to lower forms of life, and that as the cerebral hemispheres develop we become independent of it; that what we notice is the relic of a decaying faculty, not the germ of a new and fruitful sense; and that progress is not to be made by studying or attending to it. It may be that it *is* an immature mode of communication, adapted to lower stages of consciousness than ours, but how much can we not learn by studying immature stages? As well might the objection be urged against a study of embryology. It may, on the other hand, be an indication of a higher mode of communication, which shall survive our temporary connection with ordinary matter.

I have spoken of the apparently direct action of mind on mind, and of a possible action of mind on matter. But the whole region is unexplored territory, and it is conceivable that matter may react on mind in a way we can at present only dimly imagine. In fact, the barrier between the two may gradually melt away, as so many other barriers have done, and we may end in a wider perception of the unity of nature, such as philosophers have already dreamt of.

I care not what the end may be. I do care that the inquiry shall be conducted by us, and that we shall be free from the disgrace of jogging along accustomed roads, leaving to outsiders the work, the ridicule, and the gratification, of unfolding a new region to unwilling eyes.

It may be held that such investigations are not physical and do not concern us. We cannot tell without trying. In that I trust my instinct: I believe there is something in this region which does concern us as physicists. It may concern other sciences too. It must, one would suppose, some day concern biology; but with that I have nothing to do. Biologists have their region, we have ours, and there is no need for us to hang back from an investigation because they do. Our own science, of Physics or Natural Philosophy in its widest sense, is the King of the Sciences, and it is for us to lead, not to follow.

And I say, have faith in the Intelligibility of the universe. Intelligibility has been the great creed in the strength of which all intellectual advance has been attempted, and all scientific progress made.

At first things always look mysterious. A comet, lightning, the aurora, the rainbow—all strange anomalous mysterious apparitions. But scrutinized in the dry light of science, their relationship with other better-known things becomes apparent. They cease to be anomalous; and though a certain mystery necessarily remains, it is no more a property peculiar to them, it is shared by the commonest objects of daily life.

The operations of a chemist, again, if conducted in a haphazard manner, would be an indescribable medley of effervescences, precipitations, changes in colour and in substance; but, guided by a thread of theory running through them the processes fall into a series, they all become fairly intelligible, and any explosion or catastrophe that may occur is capable of explanation too.

Now I say that the doctrine of ultimate intelligibility should be pressed into other departments also. At present we hang back from whole regions of inquiry, and say they are not for us. A few we are beginning to grapple with. The nature of disease is yielding to scrutiny with fruitful result; the mental aberrations and abnormalities of hypnotism, duplex personality, and allied

[1] This is, of course, not assertion, but suggestion. It may be erroneous to draw any such distinction between animate and inanimate.

Digitized by Google

phenomena, are now at last being taken under the wing of science after long ridicule and contempt. The phenomenon of crime, the scientific meaning and justification of altruism, and other matters relating to life and conduct, are beginning, or perhaps are barely yet beginning, to show a vulnerable front over which the forces of science may pour.

Facts so strange that they have been called miraculous are now no longer regarded as entirely incredible. All occurrences seem reasonable when contemplated from the right point of view, and some are believed in which in their essence are still quite marvellous. Apply warmth for a given period to a sparrow's egg, and what result could be more incredible or magical if now discovered for the first time. The possibilities of the universe are as infinite as is its physical extent. Why should we grope with our eyes always downward, and deny the possibility of everything out of our accustomed beat.

If there is a puzzle about free-will, let it be attacked; puzzles mean a state of half-knowledge; by the time we can grasp something more approximating to the totality of things the paradoxity of paradoxes drops away and becomes unrecognizable. I seem to myself to catch glimpses of clues to many of these old questions, and I urge that we should trust consciousness, which has led us thus far; should shrink from no problem when the time seems ripe for an attack upon it, and should not hesitate to press investigation, and ascertain the laws of even the most recondite problems of life and mind.

What we know is as nothing to that which remains to be known. This is sometimes said as a truism; sometimes it is half doubted. To me it seems the most literal truth, and that if we narrow our view to already half-conquered territory only, we shall be false to the men who won our freedom, and treasonable to the highest claims of science.

I must now return to the work of this Section, from which I have apparently wandered rather far afield, further than is customary—perhaps further than is desirable. But I hold that occasionally a wide outlook is wholesome, and that without such occasional survey, the rigid attention to detail and minute scrutiny of every little fact, which are so entirely admirable and are so rightly here fostered, are apt to become unhealthily dull and monotonous. Our life-work is concerned with the rigid framework of facts, the skeleton or outline map of the universe: and, though it is well for us occasionally to remember that the nature and colour and beauty which we habitually ignore are not therefore in the slightest degree non-existent, yet it is safest speedily to return to our base and continue the slow and laborious march with which we are familiar and which experience has justified. It is because I imagine that such systematic advance is now beginning to be possible in a fresh and unexpected direction that I have attempted to direct your attention to a subject which, if my prognostications are correct, may turn out to be one of special and peculiar interest to humanity.

THE LATE PROF. MARTIN DUNCAN, F.R.S.

WE have already announced the death of this well-known geologist; and now give a brief account of his services to science.

As a Fellow of the Royal, Linnean, Geological, and Microscopical Societies, and for some time President of the two last-named of these, it goes without saying that his attainments were of no mean order. Educated for the medical profession at King's College, London, he matriculated at the London University in 1841, taking honours in anatomy and physiology in 1844, and the degree of Bachelor of Medicine in 1846, in which year also he qualified as a Member of the Royal College of Surgeons. His early life was passed at Rochester with Dr. Martin, and at Colchester, where he was in practice for some years, and where he so won the esteem of all who knew him that he was elected Mayor of that city. Fascinated with the study of geology, and impressed with the idea that to make any mark in the scientific world a man should take up some *spécialité*, he not only obtained a broad grasp of his favourite subject, but devoted himself especially to the study of fossil corals and echinoderms, to which at intervals he published numerous [illegible] indeed, for many years, and up to within a comparatively short period of his death, he continued to work at his special subject, and contributed many important papers to the *Annals and Magazine of Natural History*, the Journal of the Geological Society, the *Geological Magazine*, *Quarterly Journal of Microscopical Science*, the Philosophical Transactions and Proceedings of the Royal Society, the Proceedings and Transactions of the Zoological Society, and the Journal of the Linnean Society.

He soon found that residence out of London, away from scientific societies and important works of reference, was a great obstacle to work, and that if he was to make any real progress with his special studies it was absolutely necessary for him to seek some appointment in the metropolis. Fortunately for him, as it happened, the Chair of Geology at King's College became vacant, and he was appointed to fill it. This at once gave him the opportunity he had so long hoped for, and the preparation of his lectures proceeded side by side with much useful work, which, by degrees, he found time to publish. Such, for example, was his account of the Madreporaria collected during the expedition of H.M.S. *Porcupine*, which appeared in the Transactions of the Zoological Society (Part 1, vol. viii. p. 303, &c., and Part 2, vol. x. p. 235, &c.); his description of deep-sea and litoral corals from the Atlantic and Indian Oceans (Proc. Zool. Soc., 1876, p. 428, &c.); and his important revision of the Echinoidea, printed in the Journal of the Linnean Society, of which it occupied four numbers.

This was all strictly scientific work, but by no means represented all that he accomplished. As a popular exponent of the teaching of geology and zoology, especially in regard to the lower forms of life, he published many excellent articles which were designed to awaken an interest in subjects little investigated, though well worthy of attention.

Lucidly written and full of facts, these articles were at once instructive and suggestive, and from a teachers' point of view did more to educate youthful naturalists and encourage research than any of his more scientific papers, which, being of a more technical character, were less acceptable to the majority of readers because less intelligible to them.

Of this class were his articles on "Corals and their Polypes" (*Intellectual Observer*, 1869, pp. 81-91, 241-50, with two coloured plates); "Studies amongst Amœbæ" (*Popular Science Review*, 1877, with two plates), and "Notes on the Ophiurans, or the Sand and Brittle Stars" (*Popular Science Review*, 1878, with a plate).

His attention, however, was not confined to invertebrate zoology or geology. In 1878 he commenced the publication, in six volumes quarto, of a popular "Natural History," which had the merit of being written by a number of able specialists upon a comprehensive plan under his direction, and, while taking upon himself the laborious duties of editor-in-chief, he contributed many of the sections himself. Thus, while securing the co-operation of such well-known zoologists as the late Prof. W. K. Parker, the late Mr. Dallas, Prof. Seeley, Prof. Boyd Dawkins, Dr. H. Woodward, Dr. Murie, Mr. H. W. Bates, and Mr. R. B. Sharpe, he himself undertook the preparation of the articles on Apes and Monkeys, Lemurs (part), Edentata, Marsupialia, Reptilia, and Amphibia. He also wrote the introduction to the Invertebrata, and the articles Vermes, Zoophytes, and Infusoria which appeared in the last volume, published in 1883.

For an excellent summary of marine zoology, in which the appearance, structure, and habits of such animals and plants as may be found upon our coasts are well described, the reader may be referred to a little volume by Dr. Duncan, entitled "The Sea shore." It forms one of a series of "Natural History Rambles," issued a few years since by the Society for Promoting Christian Knowledge, and, for the amount of information which it

Digitized by Google

contains, as well as for its lucid expression, deserves to be better known.

Dr. Martin Duncan was undoubtedly one of the working bees in the great hive of science; and in his own quiet, unostentatious way has stored up a considerable amount of material the value of which will be more and more appreciated as those for whose benefit it was accumulated come to examine and understand it.

In his ardent devotion to science, and patient industry in spite of trials and troubles which would have deterred many less earnest workers, he set a bright example, which those of a younger generation of naturalists would do well to follow.

NOTES.

IT seems that those members of the Government, whichever they may be, who are responsible for buildings for science and art, have determined to erect new galleries for the Art Museum at South Kensington; practically to cover all the ground which is supposed to be applicable for art purposes there. These buildings are to cost some £400,000, and, when this money is spent, we suppose the South Kensington Art Museum will be finished. We suppose, also, that the building of a Science Museum will, by this action, be delayed for another twenty years. This will be a great victory for art, and will afford another interesting example of the results of the way in which matters scientific are managed in this country.

MR. EDGAR THURSTON, Curator of the Government Museum at Madras, has been appointed to officiate for two years for Dr. Watt, at Calcutta, in reporting on economic products and organizing collections of products and manufactures for the Calcutta and other Indian Museums; his duties at Madras being in the meantime discharged by Dr. Warth, of the Geological Department.

PROF. GOEBEL, of Marburg, has been appointed to the Chair of Botany at Munich in succession to the late Prof. Naegeli.

WE regret to announce the death of Dr. Weiss, the Professor of Botany and Director of the Plant-Physiological Institute of the University of Prague.

THE late Cardinal Haynald's important herbarium and botanical library has been placed in the National Museum at Budapest.

WE learn from Madras that the observations made under the direction of the late Mr. Pogson are in a forward state of reduction, and that the real activity of the Observatory is not to be measured by the fact that the last published volume of observations contains the record of those made in 1870. The funds at the disposal of the Madras Observatory have not permitted the regular and early publication of the masses of observations which the industry of Mr. Pogson and his assistants has accumulated, and the scheme which the Director proposed to himself did not permit him to give, from time to time, an abstract of his work through the ordinary and recognized channels open for the dissemination of astronomical results. Mr. Michie Smith writes that the "Variable Star Atlas" alone contains the observations of about 60,000 stars, made and reduced by Mr. Pogson. We may express an earnest wish that no long time may be suffered to elapse before astronomers have an opportunity of judging the value of this mass of material in an interesting branch of astronomical inquiry.

UNDER the McKinley *régime* it seems to be a very generous thing for an American *savant* to communicate a paper to a British society. One of them writes as follows to the *Nation*:—"A learned society of Scotland, in pursuance of its liberal policy, mailed to me fifty author's copies of a paper which had been honoured by admission to its Transactions. The bundle came to the local post-office this week opened, and accompanied by a slip giving the package a 'commercial value' of twelve dollars, and assessing a duty of 25 per cent. The local collector of customs thinks that I am resisting the just claims of a hard-working Government in delaying payment; but curiosity as to how they discover the commercial value of a paper whose real audience might, I think, be numbered on the fingers of the two hands, has led me to appeal the case."

Science states that the executors of the estate of the late William B. Ogden, the first Mayor of Chicago, have selected the University of Chicago as one of the beneficiaries, giving it a scientific school. The gift, which will amount to from three hundred thousand to half a million dollars, will endow a separate department of the University, to be called the Ogden Scientific School, its purpose being to furnish graduate students with the best facilities possible for scientific investigation by courses of lectures and laboratory practice. The income of the money appropriated is to be devoted to and used for the payment of salaries and fellowships, and the maintenance of laboratories in physics, chemistry, biology, geology, and astronomy, with the subdivisions of these departments. A large share of the time of the professors in the school is to be given to original investigation, and encouragement of various kinds is to be furnished them to publish the results of their investigations, a portion of the funds being set apart for the purpose of such publication.

IT seems as if in time the publishers of sea-side guides may realize that some people who require a holiday are intelligent, possess eyes, and perchance even some acquaintance with natural history. We have just received a copy of Johnson's illustrated "Visitors' Companion" to Eastbourne and its vicinity, which contains, besides the matter usually supplied, an account of the flora, consisting of 291 varieties of wild flowers, 9 orchids, 18 ferns, 12 mosses and their allies, 34 varieties of sea-weeds (with directions for collecting and preserving them); particulars are also given of 56 varieties of butterflies (with time of appearance), 45 varieties of moths (with time of appearance, and how to catch them by the electric light), 29 varieties of wild bees, pebbles, fossils, land and freshwater mollusca, a brief geological survey of the district, and an extensive list of wild birds which frequent the neighbourhood, together with a guide to fresh and salt water fishing. Have we to thank Prof. Huxley's local influence for this?

AN exhibition of the successes in acclimatization achieved in Russia will be opened at Moscow, in connection with the International Congresses of Zoology and Prehistoric Archæology and Anthropology which will be held in the Russian capital in August 1892. The results of the numerous experiments in acclimatization of a great variety of plants which have been made during the last twenty-five years, especially in the Asiatic dominions of the Empire, will be exhibited.

IN a Vice-Presidential Report to the U.S. National Geographic Society, on the "Geography of the Air," Lieut. A. W. Greely reviews the progress of meteorological science during the past year, chiefly with reference to the work of American meteorologists. Referring to the recent controversy on the causes of cyclones and anticyclones, he says:—"The status of the meteorological discussion which has been going on for some time seems to be this. A number of men, applying themselves to investigation in separate branches or stages of the same science, are attempting to reconcile their views, which, based as they are upon entirely different processes of investigation, are not entirely accordant. Some at least of these writers are still apparently groping in the preliminary, the 'natural history' stage of the science of meteorology, while one alone stands as the exponent of the 'natural philosophy' of meteorology." This view seems somewhat inappreciative, and the account given of Dr.

Digitized by Google

Hann's work inadequate and not quite correct. Dr. Hann's memoir demonstrated that the temperature conditions of anti-cyclones, and probably extra-tropical cyclones, are inconsistent with the convectional hypothesis as worked out by Prof. Ferrel, and he suggested as an alternative that their cause is to be sought in the general circulation of the atmosphere. But he did not originate this view, which had been put forward long before by Werner Siemens; nor did he attempt to develop it. It is incorrect, therefore, to represent this hypothesis as the main object of his memoir. In connection with the work of the Weather Bureau, of which Lieut. Greely is Director, he notices the experiments of Prof. Marvin on wind pressures and velocities, which confirm the results of some previous experimenters in proving that the indications of the Robinson anemometer are too high; also that pressures computed from velocities by the usual formula are much in excess of the truth; the result being that the pressure computed from the readings of the Robinson anemometer, when the actual velocity is sixty miles per hour, is 50 per cent. too high. Other subjects briefly noticed are Finley and Hazen's work in connection with tornadoes, and Prof. Russell's on cold waves.

IN a pamphlet entitled "Physical and Geological Traces of Permanent Cyclone Belts," Mr. Marsden Manson treats of a somewhat large subject in the small space of ten pages. Starting with the assumption that the main features of the barometric zones of the earth have been the same throughout past ages as they are at the present day, and that there has always been a belt in the north temperate zone, between 50° and 60° N. lat., which is the mean track of maximum cyclone frequency and low mean pressure, he infers that, owing to the diminished pressure, this has always been an axis of upheaval, and at the same time, owing to excessive precipitation, a zone of maximum denudation. His ideas are apparently suggested by the geological structure, the orographic and meteorological features of North America, and little or no attempt is made to verify his inferences by the geological and meteorological conditions of Europe and Asia, which hardly seem to bear out his hypothesis. Thus he instances the Archæan axis of Canada as the secular result of upheaval and denudation along an axis roughly coinciding with the average storm track; but he omits to show any similar relations between the Archæan rocks of Bohemia or the Alpine chain and the average course of storms in Europe. It is, however, altogether premature to criticize a theory put forward in so crude a stage of development, and it is hard to see what service can be rendered to science by such premature publication.

DR. W. DOBERCK has published the observations made at the Hong Kong Observatory in the year 1889. Returns were received from forty land stations, and extracts from logs of ninety-three ships which visited Chinese waters were collected during the year, and will be utilized in investigations of the meteorology and typhoons of the Eastern seas. The stations in connection with maritime meteorology extend to the Island of Luzon, and a most valuable station has been established on the Island of Formosa, by the Chinese Maritime Customs. The observations of the rain-band have been regularly continued, and have been found of use both in prediction of fine weather and of heavy thunderstorms. An advance Report issued for 1890 shows that considerable improvement in the storm-warning service has been effected by the connection of the Observatory with the telegraph offices. A committee of inquiry which sat in the early part of 1890, has recommended that more financial and other assistance be given to Dr. Doberck in carrying out his work.

THE Central Meteorological Office of Paris has recently published its *Annales* for the year 1888, consisting of three large quarto volumes. Vol. i. contains:—A discussion by M. Fron on the character of the thunderstorms of the years 1887 and 1888, with charts for each day on which such storms occurred; a review by M. Moureaux of the magnetic observations at Park of Saint Maur, together with *facsimile* curves of the most interesting disturbances. Owing to an agreement with Greenwich Observatory, the curves published in this country and in France will generally correspond to the same disturbances, and will therefore allow of interesting comparisons. *Résumés* of the magnetic observations made at 53 other stations in France are also published. A discussion by M. Angot of the phenological and other periodical phenomena during the years 1886 and 1887. These observations have now been continued for eight years. M. Angot has also studied the effect of the amount of cloud on the daily variation of temperature at Paris. A paper by M. Raulin on the seasonal rainfall of various countries in Europe, in which he shows that when a number of years are taken into consideration the condensation of vapour follows a regular seasonal range, with a minimum in winter and a maximum in summer, where the range is not interfered with by secondary causes, such as proximity to the sea, &c. M. Teisserenc de Bort presents a paper on the mode of formation of types of isobars, and on the theory of the general circulation of the atmosphere, illustrated by diagrams. Vol. ii. contains the observations made at various stations and mountain observatories, including also several stations in Algeria, Egypt, Panama, &c. Vol. iii. contains values of rainfall at a large number of stations, with monthly, seasonal, and annual charts. The actual number of stations reaches nearly 1800, and daily values are published for 925 stations.

A REMARKABLE weather change is reported to have occurred at Orenburg on November 19, 1890. After a temperature of 3° C., with heavy rain, there was a fall to − 30° C. in 20 minutes. Some thirty Kirghises, who were returning to Orenburg, were drenched with the rain, then frozen on their horses. Ten of them had been found, and the others were being sought for. Many horses and other animals succumbed to the cold.

SNOW-DRIFTS are found a serious disturbance of the Russian railway system. With a view to forecasting such occurrences, M. Sresnewskij has lately collected information about snow-drifts on the Russian lines during 1879-89 (*Rep. für Met.*). The drifts occur in the Northern and Eastern Governments, chiefly with south-west wind, but in Southern Russia with north-east. In the north, greater gradients are required than in the south. The maximum of the drifting is in mid-winter, but there is more in the second half of winter than in the first, that having more snow. In course of winter the snow grows in thickness, so that in March there is more to drift than in December. The marked diminution of drifting in February is due to the less wind in that month (a fact not yet explained, as the number of cyclones shows no decrease). Two kinds of drifting are distinguished; it may be only or chiefly snow lying on the ground that is whirled and carried along, or the wind may drive falling snow. There are most drifts in the months that have least snowfall and the smallest number of days of snow. The snow-drifts in South Russia with north-east wind are chiefly connected with anticyclones in the central region, or cyclones on the southern border; those in the east and north with cyclones in European Russia. In Central Russia they occur with cyclonic winds of various direction, seldom with anticyclones.

AN investigation (more comprehensive than the previous ones by Forel, Fritz, and others) of the variations of Alpine glaciers, has been recently made by Herr Richter, of the German and Austrian Alpine Club. To six advances of glaciers, previously known, he adds three, and his account of the six differs somewhat from previous ones. The dates of commencement of the

Digitized by Google

nine advances are 1592, 1630, 1675, 1712, 1735, 1767, 1814, 1835, 1875 (?). The following are some of Richter's conclusions:—Glacier advances recur in periods varying between twenty and forty-five years; on the average of three centuries, thirty-five years. The advances are not all of equal intensity, nor alike in their progress. Nor is the intensity in a given advance-period the same in all glaciers. In the case of some glaciers, a period is occasionally skipped, the advance or retirement being very weak, so that the thirty-five years period gives place to one of seventy years. The glacier variations correspond, in general, with Brückner's climate variations. The glacier advance generally begins a few years after the moist and cool period has set in. There is no good reason to suppose that, in historic time, before the sixteenth century, the Alpine glaciers were smaller than now, or that variations occurred of different order and period from those of the last 300 years. About 1880, the earth was passing through a moist and cold period, which should have resulted in a general advance; but the advance has been but slight hitherto, and, in the Eastern Alps, mostly absent. The cause of this is not at present clear, but the mild nature of this last cold period may have something to do with it.

THE bacillus of tuberculosis, it is known, is often to be found in places lived in by consumptives. Herr Prausnitz has lately collected the dust in various compartments of trains which often convey patients from Berlin to Meran, and inoculated a number of guinea-pigs with it. Two, out of five compartments so examined, were found to contain the bacillus; the dust of one rendered three out of four guinea-pigs tuberculous; that of the other, two. The animals were killed after ten to twelve weeks, but in no case was the disease very advanced; the author supposes the number of bacilli to have been but small. The facts, however, seem to point to the necessity of disinfection of such railway carriages, especially the carpets or mats.

TO the usual well-known ways of stimulating muscles to contraction, viz. electrical, thermal, mechanical, and chemical, M. D'Arsonval has recently added that by means of light. He could not, indeed, get any contraction in a fresh frog-muscle, when he suddenly threw bright light on it in a dark chamber; but having first in darkness stimulated a muscle with induction currents too weak to give a visible effect, and then suddenly illuminated the muscle with an arc light, the muscle showed slight tremulation. Not thinking this conclusive, however, M. D'Arsonval attached a muscle to the middle of a piece of skin stretched on a funnel, and connected the tube of the funnel by means of a piece of india-rubber tube with the ear. The muscle being now subjected to intense intermittent light, he heard a tone corresponding to the period of illumination, and this ceased when the muscle was killed with heat. Arc light was used, which was concentrated by a lens and passed through an alum-solution to stop the heat rays.

FOR nearly two years there has been at work in Denver, Colo., an automatic refrigerator system, which seems to be thoroughly successful. Ammoniacal liquor in the proportion of 29 parts pure ammonia to 71 parts water, is forced through a main to the point where refrigeration is desired; a sudden increase of space is afforded there for quick vaporization, and after absorption by water, the liquid returns by suction to the central station. There are two miles of mains having connection with twenty-nine boxes, each containing a grill near the top to which the liquor is admitted. The space formerly devoted to ice is a clear gain; and the temperature, instead of being a varying quantity, dependent on the arrival of the ice man, and never below 40° F., can be reduced to any degree above 25° F. in a few minutes, and kept within 2° of the same. The air is dry, sweet, and clean; the moisture collects on the grill as frost. In one experiment a piece of meat was kept six months and then cooked and eaten, and it seemed no way different from fresh meat.

THE French Société de l'Encouragement lately offered a prize of 1000 francs for conservation of potatoes and other vegetables. Four of the five applicants used some isolating substance (wood-ash, sawdust, rye-straw with sand). M. Schribaux, who gained the prize, puts potatoes for ten hours in a 1½ per cent. solution of commercial sulphuric acid to kill the buds (a 2 per cent. solution for thick skins). The potatoes are taken out and thoroughly dried, and they will keep without alteration more than a year. The same solution serves for repeated immersions, the concentration remaining constant. The process is not applicable to onions. Another prize by the same Society (3000 francs) is awarded to M. Candlot for a memoir treating of the action of sea-water on cements. He shows that the sulphate of lime resulting from decomposition of sulphate of magnesia by lime-salts of the cement combines with aluminate of lime to give a double crystalline salt containing half its weight of water. The crystallization of a salt so greatly hydrated involves considerable swelling, and this accounts for the disaggregation of cements in marine work. M. Candlot has observed the curious fact that over-baked lime, which takes several days to extinguish in water, is extinguished in a few minutes in a 3 per cent. solution of chloride of calcium. This is thought to have important practical bearings.

M. RASPAIL has lately called attention, in the Zoological Society of France, to the serious diminution of birds in that country through destruction of their nests. Some insectivorous species are becoming very rare, while the ravages of parasites on useful plants are extending. Boys, of course, do a great deal of the mischief; and of the various animals which attack nests (the squirrel, the hedgehog, the dormouse, the magpie, &c.) M. Raspail regards the cat as the worst offender. On a recently-wooded property of about 7 acres he observed last year as follows:—Out of 37 nests, carefully watched, only 8 succeeded; 29 were destroyed, 14 of these by the cat, though effort had been made to ward off this insatiable marauder. On a large property in the centre of a village the owner had about 80 cats annually caught in traps. The place having lately changed hands, the gardeners estimate that more than 100 nests were destroyed last year, three-fourths of these by cats. M. Raspail advocates a rigorous application of the law for protection of insectivorous species, the disqualification of the cat as a domestic animal, and the giving of prizes to foresters and others for destruction of all animals which prey on eggs and young in the nest.

TOBACCO fermentation, a very essential process, is brought about by firmly packing ripe tobacco in large quantities. It had been generally supposed that the fermentation is of purely chemical nature, but Herr Suchsland, of the German Botanical Society, finds that a fungus is concerned in it. In all the tobaccos he examined, he found large quantities of fungi, though of only two or three species. Bacteriaceæ were predominant, but Coccaceæ also occurred. When they were taken and increased by pure cultivation, and added to other kinds of tobacco, they produced changes of taste and smell which recalled those of their original nutritive base. In cultivation of tobacco in Germany it has been sought to get a good quality, chiefly by ground cultivation, and introduction of the best kinds of tobacco. But it is pointed out that failure of the best success may be due to the fact that the more active fermenting fungi of the original country are not brought with the seeds, and the ferments here cannot give such good results. Experiments made with a view to improvement on the lines suggested have apparently proved successful.

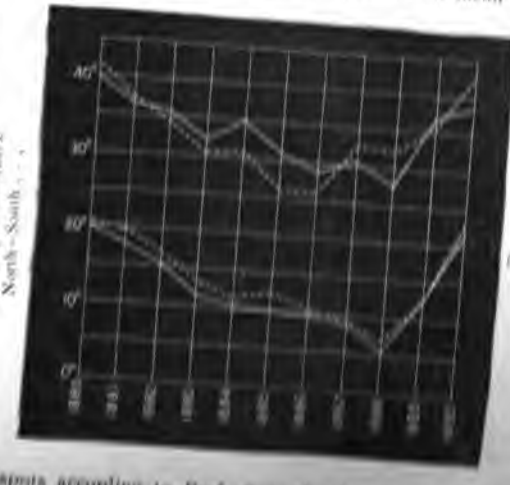
A PROFITABLE industry, little heard of, is carried on among the hills of Connecticut (*Sci. Am.*). It is the manufacture of birch oil, which is used largely for confectionery, and gives a perfect wintergreen flavour. There are eight mills in the State [illegible] first built only ten years ago. Birch brush, without [illegible] age, and not over 2½ inches in diameter, from the black, mountain or sugar birch (not the yellow or white), is chopped up and [illegible] with water in tanks. The steam, passing through an [illegible] pipe near the top, is condensed in a coil immersed in [illegible] water, and drops into a glass jar. The oil is much [illegible] than water, and in the crude state is of copper hue. [illegible] mills work only from October to April. A good deal of [illegible] birch oil is used in tanning leather to imitate Russia [illegible].

We have just received the Report for 1890 of the Botanical [illegible] Club of the British Isles. There are about fifty [illegible], and a list of the plants that are wanted is sent out [illegible] spring. The Secretary is Mr. Charles Bailey, Ashfield [illegible] Road, Whalley Range, Manchester. The distributor [illegible] year was the Rev. E. T. Linton, one of our most painstaking British botanists, and the Report is edited by him. The [illegible] of specimens received was 4100, from twenty-six contributors. The most interesting novelty of the year is an [illegible] found at the head of Ribblesdale, in Yorkshire, which is [illegible] allied to, but not quite identical with, *A. norvegica*, [illegible] only within the British area in the Shetland Islands and [illegible], and *A. silicata*, known only in County Sligo. Mr. [illegible] names it as *A. gothica*, Fries., but that plant is an [illegible], while the Ribblesdale plant is a perennial. It is, in [illegible] form, about half-way between *norvegica* and *gothica*. [illegible] forty-eight pages of the Report, eleven are occupied by [illegible] a new general working up of the British Rubi is much [illegible], and it is evident the different referees to whom the [illegible] have been sent do not use some of the names with [illegible] application or range of significance. What beginners [illegible] good typical specimens of the most distinct forms. To [illegible] the intermediate connecting links before they know [illegible] the typical sub-species only bewilders them. In [illegible] difficulty is that it is often impossible to determine a [illegible] satisfactorily without seeing it in three stages—flower, [illegible] and mature fruit—and nearly all the specimens sent [illegible] are in a single stage. The above remark applies [illegible] and Hieracia, concerning which there are eleven [illegible] in the Report, none of which tend to any real en[illegible]. To Rosa the same remark applies as to Rubi; [illegible] a laborate monograph, now fairly started [illegible] in type. Three other sets of plants are at present [illegible] from the members, *i.e.* hybrid willows, [illegible] and Potamogetons. At the end of the Report [illegible] of new county records.

[illegible] Zoological Society's Gardens during the [illegible] Capuchin (*Cebus fatuellus* ♀) from [illegible] Phyllis Duncan; a Red-bellied [illegible] from Trinidad, a Golden Agouti [illegible], a West Indian agouti [illegible] the West Indies, one Four-banded [illegible] from Brazil, [illegible] Mr. R. H. L. [illegible] European, presented by Captain Taylor; a Common Chameleon (*Chamæleon vulgaris*) from North Africa, a Dwarf Chameleon (*Chamæleon [illegible]*) from South Africa, presented by Captain Wood; two Common Chameleons (*Chamæleon vulgaris*) from North Africa, presented by Mr. F. Palmer; an Egyptian Ichneumon (*Herpestes ichneumon*) from Spain, a Black-headed Caique (*Caica melanocephala*) from Demerara, deposited; a Yak (*Poëphagus grunniens*), born in the Gardens.

OUR ASTRONOMICAL COLUMN.

PERIODIC VARIATIONS IN THE LATITUDE OF SOLAR PROMINENCES.—From a paper by Prof. Ricco, in *Comptes rendus* for August 3, it appears that the mean latitude of solar prominences varies periodically in the same way as that of spots. During the last eleven years observations of the form, position, and dimension of solar prominences have been made at Palermo on 2207 days, with the same refractor and spectroscope. In this period 7664 prominences have been observed, having a height equal to or greater than 30″. Neglecting a few irregularities, the observations show that about the time of maximum solar activity prominences occur nearest the sun's equator; the mean latitude for both hemispheres in the second year after the last maximum being 27°·5. There is then a rapid general increase in the latitude of most frequent occurrence up to the minimum epoch, the mean latitude for both hemispheres in the year following the last minimum—that is, in 1890—being 41°·4. In other words, up to the commencement of the minimum period prominences approach the equator. They then appear in high latitudes, to descend again to the equator in an eleven-year cycle. The intimate relation that exists between this variation and that observed in the distribution of spots is evident from an inspection of the accompanying figure, which represents the mean latitudes



of spots according to Prof. Spörer's observations, and those found for prominences by Prof. Ricco. The pairs of lines curves run almost parallel to each other, and are separated by an approximately equal number of degrees at all points. It is worthy of remark that the photographs of the solar corona recently investigated by Prof. Bigelow exhibit a [illegible] latitude which is most probably connected with the [illegible] variations of sun-spots and prominences.

THE HISTORY OF HUMAN MARRIAGE

EDWARD WESTERMARCK, Ph.D.

[illegible] Lecturer in Sociology in the University of London.

[illegible] should command the serious [illegible]

[illegible] could scarcely be a [illegible] most difficult and [illegible] convince the reader that [illegible] anthropo- [illegible] way [illegible] Clear and becom- [illegible] affords a model for future [illegible]

[illegible] comes from the comparatively [illegible] Spencer, Tylor, Lubbock, and [illegible] Westermarck: [illegible] more than possible [illegible] favour of the new- [illegible] be treated at once briefly and [illegible] theme: and not the [illegible] reproachless on [illegible]

[illegible] the appearance of Mr. McLennan's work on 'Primitive Marriage' there has been [illegible] Dr. Westermarck's 'History of [illegible] suppose that his [illegible] book will find a host of readers even among [illegible] the theories that may be drawn from them."

NEW VOLUME OF NATURE SERIES.

Just ready. 8vo. Cloth, 12s. 6d.

RIGHT HAND, LEFT HANDEDNESS. By Sir DANIEL WILSON, LL.D., F.R.S.E., President of the University of Toronto.

Just ready. 8vo. Cloth, 12s. net.

A POSITIVE THEORY OF CAPITAL. By EUGEN V. BÖHM-BAWERK, Member of the Austrian Cabinet of Finance, etc. Honorary Professor of Political Economy in the University of Vienna. Translated, with a Preface and Appendix, by WILLIAM SMART, M.A., Lecturer on Political Economy in Queen Margaret College, Glasgow.

Capital and Interest," [illegible] English [illegible] wisits

ACADEMY.—"In [illegible] its name is also [illegible] essay. His preface, and [illegible] digest, and the actual translation are all [illegible] able. We owe [illegible] an interesting addition to English students a treatise which is certainly well worth attention as [illegible] an ingenious enough, and which, although its central theory is based, as the author frankly avows, [illegible] Menger, has carried those ideas further and given them a special application."

UNIFORM WITH THE ABOVE.

8vo. Price reduced to 12s. net.

CAPITAL AND INTEREST: a Critical History of Economical Theory. By EUGEN [illegible] BÖHM-BAWERK, Honorary Professor of Political Economy in the University of Vienna. Translated, with a Preface and Appendix, by WILLIAM SMART, M.A., Lecturer on Political Economy in Queen Margaret College, Glasgow.

NEW EDITION, REVISED.

Crown 8vo, Cloth, 10s. 6d.

A COURSE OF PRACTICAL INSTRUCTION IN BOTANY. By F. O. BOWER, D.Sc., F.R.S., Regius Professor of Botany, Glasgow.

NATURE.—"Everyone perusing the volume must be impressed with the high standard of its educational value. Teacher [illegible] in this country are alike to be congratulated upon its publication."

ACADEMY.—"The work is one which should be in the hands of every practical botanist."

SATURDAY REVIEW.—"The types are good, easily obtained, and the roughly worked out. . . . There is no padding, [illegible] to the point, and presumes the presence of the plant concerned and the instruments in hand. We regard the absence [illegible] instructions and of [illegible] padding as important preventives of cram, and it should be clearly borne in mind that laboratory [illegible] suffers especially by the opening up of royal roads."

BY SIR ARCHIBALD GEIKIE, LL.D., F.R.S.

New and Revised Edition. Globe 8vo, 5s. 6d.

OUTLINES OF FIELD GEOLOGY. By Sir ARCHIBALD GEIKIE, LL.D., F.R.S., Director-General of the Geological Survey of Great Britain and Ireland.

*This volume has now been thoroughly revised and [illegible] which has been [illegible] in the Light of recent research [illegible] the Author's Preface.

UNIVERSITY COLLEGE, LONDON.

The SESSION of the FACULTIES of ARTS and LAWS and of SCIENCE (including the Indian and Oriental Schools and the Department of Fine Arts) will begin on OCTOBER 2. The Introductory Lecture will be given at 8.30 p.m. by Prof. W. F. R. WELDON, M.A., F.R.S.

PROFESSORS.	
F. ALTHAUS, Ph.D.	German.
J. HUDSON BEARE, B.Sc.	Engineering and Mechanical Technology.
EDW. SPENCER BEESLY, M.A.	Ancient and Modern History.
CECIL BENDALL, M.A.	Sanskrit.
Rev. T. G. BONNEY, D.Sc., F.R.S., F.G.S.	Geology and Mineralogy (Yates-Goldsmid Professorship).
T. W. RHYS DAVIDS, LL.D., Ph.D.	Pali and Buddhist Literature.
ANTONIO FARINELLI, L.B.	Italian Language and Literature.
J. A. FLEMING, M.A., D.Sc.	Electrical Technology.
G. C. FOSTER, B.A., F.R.S.	Physics (Quain Professorship).
H. S. FOXWELL, M.A.	Political Economy (Newmarch Professorship).
ALFRED GOODWIN, M.A.	Latin. Greek.
ALEXANDER HENRY, M.A., LL.B.	Jurisprudence and Constitutional Law and History.
M. J. M. HILL, M.A.	Mathematics.
W. P KER, M.A.	English Language and Literature (Quain Professorship)
H. LALLEMAND, B.-ès-Sc.	French Language and Literature.
A. LEGROS	Fine Arts (Slade Professorship).
Rev. D. W. MARKS	Hebrew (Goldsmid Professorship).
A. F. MURISON, M.A.	Roman Law.
F. W. OLIVER, B.A., D.Sc.	Botany (Quain Professorship).
KARL PEARSON, M.A., LL.B.	Applied Mathematics.
R. S. POOLE, LL.D.	Archæology (Yates Professorship).
J. P. POSTGATE, M.A.	Comparative Philology.
W. RAMSAY, Ph.D., F.R.S.	Chemistry.
CHARLES RIEU, Ph.D.	Arabic and Persian.
G. CROOM ROBERTSON, M.A.	Philosophy of Mind and Logic (Grote Professorship).
E. A. SCHÄFER, F.R.S.	Physiology (Jodrell Professorship).
T. ROGER SMITH, F.R.I.B.A.	Architecture.
L. F. VERNON HARCOURT, M.A., M.Inst.C.E.	Civil Engineering and Surveying.
W. F. R. WELDON, M.A., F.R.S.	Zoology and Comparative Anatomy (Jodrell Professorship).
WATSON SMITH, F.C.I., F.I.C. (Lecturer)	Chemical Technology.
HUGH STANNUS, F.R.I.B.A. (Lecturer)	Applied Art.

Scholarships, &c., of the value of £2000 may be awarded annually. The Regulations as to these, and further information as to Classes, Prizes, &c., may be obtained from the Secretary.

J. M. HORSBURGH, M.A., Secretary.

UNIVERSITY COLLEGE, LONDON.

LECTURES ON ZOOLOGY.

Prof. W. F. R. WELDON, M.A., F.R.S., will deliver during the ensuing Session a Course of Lectures on the DECAPOD CRUSTACEA, intended specially for Senior Students who intend to pursue original investigations in Zoology. The Lectures will be given twice weekly, commencing SATURDAY, OCTOBER 17, at 10 a.m.

The General Course of Lectures on Zoology, suitable for Students preparing for the various Examinations of the University of London, commences MONDAY, OCTOBER 5, at 4 p.m.

THE YORKSHIRE COLLEGE, LEEDS.

Applications are invited for the Appointment of LECTURER on GEOLOGY for one year from October 1, at a Stipend of £100, for which 10 Lectures on the Geology of Coal Mining and 30 Lectures on Geology as connected with the Agricultural Course will be required. Opportunity will be given for Extension Lecturing in Yorkshire, for which a payment of £2 per Lecture will be made. The Lecturer would be required to reside in or near Leeds during the six winter months. The Appointment will probably be renewable.

Applications will be received by the SECRETARY of the College up to SEPTEMBER 19

QUEEN'S COLLEGES, IRELAND.

The PROFESSORSHIP of CHEMISTRY in the Queen's College, Cork, being about to become vacant, Candidates for that Office are requested to forward their Testimonials to the UNDER SECRETARY, Dublin Castle, on or before SEPTEMBER 12, in order that the same may be submitted to His Excellency the Lord Lieutenant.

The Candidate who may be selected for the above Professorship will have to enter upon his duties on or about October 10 next.

Dublin Castle, August 17, 1891.

FIRTH COLLEGE, SHEFFIELD.

The Council of Firth College propose to appoint an ASSISTANT DEMONSTRATOR IN CHEMISTRY, at a Salary of £100.

Session—OCTOBER to JUNE.

Applications must be sent, before SEPTEMBER 12, to the REGISTRAR, from whom further particulars may be obtained.

LIVING SPECIMENS FOR THE MICROSCOPE.

Volvox globator, Asplanchnopus myrmeles, Lacinularia socialis, Plumatella repens, Paludicella Ehrenbergi, and other beautiful specimens of Pond-life, 1s. per Tube, with Drawing and Description. Amœba, Hydra, Vorticella, &c., for Students.

List Post Free.

THOMAS E. BOLTON,
FARLEY ROAD, MALVERN LINK.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF.

COUNTY OF GLAMORGAN.

The Council of the University College of South Wales and Monmouthshire is prepared to appoint the following Members of a Staff of Travelling Teachers in Technical Subjects for the County of Glamorgan:—

A Lecturer in Mathematics and Theoretical Mechanics.
A Lecturer in Chemistry and Metallurgy.
A Lecturer in Geology and Mining.
One or Two Lecturers in Mechanical Engineering.

The Stipend of each Lecturer will be £200 per Annum, together with travelling expenses.

Applications, together with Testimonials and References, should be sent in not later than TUESDAY, SEPTEMBER 8, 1891, to the undersigned, from whom further information in regard to the duties of the Staff may be obtained.

IVOR JAMES, Registrar.

Cardiff, August 12, 1891.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF.

COUNTY OF MONMOUTH.

The Council of the University College of South Wales and Monmouthshire is prepared to appoint a Director of the Staff of Travelling Teachers in Technical Subjects, to be established under the provisions of the scheme of the Technical Instruction Committee of the County of Monmouth. The Stipend of the Director will be £350 per Annum.

Candidates for the post must send in their Applications, together with Testimonials and References, to the undersigned, on or before TUESDAY, SEPTEMBER 8, 1891.

For further information and for Copies of the above Scheme, apply to

IVOR JAMES, Registrar.

Cardiff, August 12, 1891.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF.

The CHAIR of GREEK is now Vacant through the Election of Prof. ROBERTS as Principal of the University College, Aberystwyth. The Council will proceed to the Appointment of the new Professor in September Next. The Stipend of the Professor will be £350 per Annum.

Applications, together with Testimonials and References, should be forwarded before TUESDAY, SEPTEMBER 8, 1891.

For further Information apply to

IVOR JAMES, Registrar.

Cardiff, August 4, 1891.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF.

The DEPARTMENTS OF ARTS, SCIENCE, AND ENGINEERING, and the NORMAL DEPARTMENTS FOR INTERMEDIATE AND ELEMENTARY TEACHERS, will open on MONDAY, OCTOBER 5, 1891. The Lectures and Classes are open to Men and Women.

For Prospectus, and information concerning Scholarships, &c., apply to

IVOR JAMES, Registrar.

University College, Cardiff, August 11, 1891.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF.

The Council of the University College of South Wales and Monmouthshire is prepared to appoint a LECTURER in GEOLOGY. The Stipend of the Lecturer will be £200 per Annum.

Applications, together with Testimonials and References, should be forwarded on or before TUESDAY, SEPTEMBER 15, 1891.

For further information apply to

IVOR JAMES, Registrar.

Cardiff, August 12, 1891.

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR.

AGRICULTURAL DEPARTMENT.

An ASSISTANT LECTURER in AGRICULTURE will be appointed in SEPTEMBER next, for one year, at a Salary of £120.

Applications must be sent in on or before SATURDAY, SEPTEMBER 5, to the undersigned, from whom information as to conditions of Appointment and Duties may be obtained.

W. CADWALADR DAVIES, Secretary and Registrar.

University College of North Wales, Bangor,
July 1, 1891.

THE VICTORIA UNIVERSITY.

The following Examinations will be held at OWENS COLLEGE (MANCHESTER), UNIVERSITY COLLEGE (LIVERPOOL), and YORKSHIRE COLLEGE (LEEDS), in SEPTEMBER.

AN ENTRANCE EXAMINATION IN ARTS (introductory to the Faculty of Medicine) on FRIDAY, September 25, and following days.

AN ENTRANCE EXAMINATION IN ARTS (introductory to the Faculty of Music) on FRIDAY, September 25, and following days.

A PRELIMINARY EXAMINATION (introductory to the Faculties of Arts, Science, and Law) on THURSDAY, September 24, and following days.

Notice (*in writing*) of intention to be present, accompanied with a List of the subjects taken, must be sent, on or before September 9, to the UNIVERSITY REGISTRAR, from whom Conditions of Entrance, and other Particulars can be obtained.

Fees for the above Examinations must be paid on or be ore September 14.

Manchester, August 1891.

UNIVERSITY COLLEGE, NOTTINGHAM,

ENGINEERING DEPARTMENT.

Professor, WILLIAM ROBINSON, M.E., Assoc.M.Inst.C.E.,

Session 1891–92 begins on MONDAY, OCTOBER 5.

Courses of Technical Instruction extending over three years are arranged for boys who have just left school and intend to take up Electrical, Mechanical, or Civil Engineering. These include Drawing Office, Laboratory and Workshop Practice, and Classes in Engineering, Mathematics, Physics, Chemistry, and Metallurgy.

The Mechanical Workshops are completely equipped with tools both in wood and iron, also forge and foundry. Instructors give special attention to Students in the various branches of Mechanical Engineering. Special facilities are offered to Students in Electrical Engineering—Electrical Laboratories including New Dynamo Room with Phœnix Dynamo, driven by Atkinson Cycle Gas-Engine, and specially fitted for Experimental Purposes. Technical Instruction in Electric and Magnetic Measurements, Dynamo-testing, &c., and Students take charge of Brush-Lighting Dynamo, trim Arc Lamps, &c., &c.

Several Scholarships and Exhibitions are offered.

For Prospectus and Fees (which are exceptionally low) apply to the SECRETARY.

THE MASON COLLEGE, BIRMINGHAM.

SESSION 1891–92.

FACULTIES OF ARTS AND SCIENCE.

The NEXT SESSION COMMENCES on WEDNESDAY, SEPTEMBER 30, 1891.

A SYLLABUS, containing Full Information as to the various Courses of Instruction, Lecture Days and Hours, Fees, Entrance, and other Scholarships, &c., is published by Messrs. CORNISH, New Street, Birmingham, Price 6*d*.; by Post, 8*d*.

Further Particulars may be obtained on Application to the SECRETARY at the College.

R. S. HEATH, Principal.
GEO. H. MORLEY, Secretary.

THE AGRICULTURAL COLLEGE, ASPATRIA.

PRINCIPAL—DR. H. J. WEBB, B.Sc.

Thorough practical and scientific Training in Agriculture. Preparation for the Colonies. Students gained the First, Third, and Fourth Scholarships of the Royal Agricultural Society, 1888. First in Agriculture Junior Scholarships, 1889; First in Agriculture Senior Scholarships, 1890.

CHEMICAL LABORATORY ASSISTANT

WANTED at UNIVERSITY COLLEGE, ABERYSTWYTH. Salary £1 Weekly. No Teaching Duties.—Address Applications, with Copies of Testimonials, to Prof. SNAPE, 5 Croxteth Road, Liverpool.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL,

ALBERT EMBANKMENT, LONDON, S.E.

The WINTER SESSION of 1891–92 will open on THURSDAY, OCTOBER 1, when the Prizes will be distributed at 3 p.m. by Sir G. M. HUMPHRY, M.D., LL.D., F.R.S.

TWO ENTRANCE SCIENCE SCHOLARSHIPS of 125 guineas and £60 respectively, open to all first-year Students, will be offered for competition. The Examination will be held on September 26, 28, and 29, and the subjects will be Chemistry and Physics, with either Physiology, Botany, or Zoology, at the option of Candidates.

Scholarships and Money Prizes of considerable value are awarded at the Sessional Examinations, as also several Medals.

Special Classes are held throughout the year for the Preliminary Scientific and Intermediate M.B. Examinations of the University of London.

All Hospital Appointments are open to Students without charge.

The Fees may be paid in one sum or by instalments. Entries may be made separately to Lectures or to Hospital Practice, and special arrangements are made for Students entering in their second or subsequent years; also for Dental Students and for Qualified Practitioners.

A Register of approved Lodgings is kept by the Medical Secretary, who also has a List of local Medical Practitioners, Clergymen, and others who receive Students into their houses.

Prospectuses and all particulars may be obtained from the Medical Secretary, Mr. GEORGE RENDLE.

G. H. MAKINS, Dean.

THE LONDON HOSPITAL MEDICAL COLLEGE.

The WINTER SESSION will commence on THURSDAY, October 1

The Hospital is the largest general Hospital in the Kingdom, and contains nearly 800 beds. Number of in-patients last year, 9806; out-patients, 120,158; accidents, 8847.

Surgical operations daily.

APPOINTMENTS.—Resident Accoucheur, House Physicians, House Surgeons, &c. Forty of these Appointments are made Annually. Numerous Dressers, Clinical Clerks, Post-mortem Clerks, and Maternity Assistants are appointed every Three Months. All Appointments are Free. Holders of Resident Appointments are also provided Free Board.

SCHOLARSHIPS AND PRIZES.—Two Entrance Science Scholarships, value £75 and £50, and Two Buxton Scholarships, value £30 and £20, will be offered for competition at the end of September to new Students. Sixteen other Scholarships and Prizes are given annually.

The Metropolitan, Metropolitan District, East London, and Great Eastern Railway Stations are close to the Hospital and College.

For further Information apply Personally or by Letter to

Mile End E. MUNRO SCOTT, Warden.

POULKOVA.—Observations publiées par Otto Struve. Vols. 1 to 7, 9, and Supplement, 11. 9 Vols. and 1 Part. St. Pétersbourg, 1869-79. £3 3*s.*

LIOUVILLE, J.—Journal de Mathématiques pure et appliquées. 1st Series, Vols. 1 to 20. 16 Vols. in 8, Half-calf, remainder in Parts. 1836-45. £9 9*s.*

GIORNALE DI MATEMATICHE, publicato per cura dei Prof. Battaglini, Janni, e Trudi. Vols. 1 to 8, 1863-70. Bound into 2 Vols., Half-calf. £2 2*s.*

MONTUCLA.—Histoire des Mathématiques. Nouvelle édition, considérablement augmentée, et prolongée jusque vers l'époque actuelle. 4 Vols., 4to. 1799-1802. £6 15*s.*

A most valuable work for the History of Mathematics. This, *the best edition*, was edited and completed by Lalande. *A Fine Copy.*

ARCHIMEDIS OPERA. 2 Vols., Folio. 1544. 30*s.*

The first printed edition of Archimedes, with the text in Greek and Latin. The Greek text, slightly water-stained, is bound in vellum; the Latin text in half-calf.

EUCLIDE MEGARENSE PHILOSOPHO, ridotto per Nicolo Tartalea. Vinegia, 1543. 30*s.* Water-stained, with writing on title: otherwise a fine copy of the very scarce folio edition of Tartalea's translation.

PAPPI ALEXANDRINI MATHEMATICAE COLLECTIONES A FREDERICO COMMANDINO IN LATINUM CONVERSAE ET COMMENTARIIS ILLUSTRATAE. Folio. Vellum, 1660. 25*s.*

A fine copy of the second edition of Pappus.

PROCLUS.—Philosophical and Mathematical Commentaries on the first book of Euclid, &c. *Printed for the Author*, 1792. 2 Vols. in 1. 35*s.*

CLAPIN, A.C.—Optical Problems. 8vo. 1850. 3*s.*

A systematic collection of examples elucidating the various theorems of Geometrical Optics—Illumination. Direct and Oblique Reflection and Refraction, Prisms, Lenses, Aberration, Dispersion of Light, Images and Vision, Telescopes, Rainbow, &c.

DE MORGAN, A.—The Book of Almanacs, with an Index of Reference, by which the Almanac may be found for every year, from any Epoch, up to A.D. 2000, &c. 2nd (and last) edit. Cloth. 1871. 6*s.*

EARNSHAW, S.—The Doctrine of Germs, or the Integration of certain Partial Differential Equations which occur in Mathematical Physics. 8vo. 1881. 3*s.*

ELLIS, R. LESLIE [1817-59].—Mathematical and other Writings, edited by Wm. Walton. Memoir by Harvey Goodwin (now Bishop of Carlisle). Portrait. 8vo, Cloth. 1863. 12*s.*

Contents:—On the Foundations of the Theory of Probabilities, the Method of Least Squares, the Integration of certain Differential Equations, the Achromatism of Eye-pieces of Telescopes and Microscopes, Lines of Curvature on an Ellipsoid, Notes on Magnetism, &c., &c.

GREGORY, DUNCAN F. [1813-44].—Mathematical Writings, edited by W. Walton, with Memoir by R. Leslie Ellis. Portrait. 8vo, Cloth 1865. 8*s.*

Contents:—On the Real Nature of Symbolical Algebra, the Solution of Linear Differential Equations with Constant Coefficients, Circular Sections in Surfaces of the Second Order, Solution of some Problems in Transversals, Solution of Partial Differential Equations, on the Impossible Logarithms of Quantities, Application of Algebraical Symbols to Geometry, &c., &c.

NEWMAN, F. W.—The Difficulties of Elementary Geometry, especially those which concern the Straight Line, the Plane, and the Theory of Parallels. 8vo. 1841 (pub. 8*s.*) 2*s.* 6*d.*

THURSDAY, AUGUST 27, 1891.

THE CONGRESS OF HYGIENE.

WE continue this week our account of the work done at this Congress. It will be clear that with the space at our disposal it is only possible to refer to few among the many subjects discussed. Among these we have selected those which have the closest connection with those researches now attracting special attention.

In regard to the subject of tuberculosis it was certainly a happy inspiration of the officials of the Bacteriological (II.) and Comparative Pathological (III.) Sections of the International Congress of Hygiene and Demography, to call a joint meeting in order that a full discussion of the scientific and practical bearings of the questions relating to "the transmission of tuberculosis from animals to man by means of flesh and milk derived from tuberculous animals" might be possible; and it was also fortunate, as far as its success was concerned, that the discussion was opened by Profs. Burdon Sanderson and Bang, each of whom in his own sphere is singularly well fitted to lay before the members of the Sections what is at present known in the medical and veterinary scientific worlds concerning this important subject. Prof. Sanderson's early researches on tuberculosis have opened up the way for much of our present knowledge on the subject, in addition to which he has watched the question most carefully through its various stages of evolution; whilst Prof. Bang, by his numerous practical observations and scientific experiments, has given a completeness to our knowledge which has not been attained as the outcome of the work of any other observer.

The discussion on this question afforded another instance of the intimate connection between the purest research and the most practical affairs of every-day life.

Thus from the tenor of the discussion it may be gathered that the danger arising from the ingestion of tuberculous milk and meat has probably been exaggerated.

Some of those who took part in the discussion, for example, seemed to doubt whether primary tuberculosis of the alimentary canal—*i.e.* tuberculosis confined to this region and evidently the result of infection through the mucous membrane—was ever met with in adults, and even whether it was of very frequent occurrence in the child; whilst other speakers were able to instance out of their own experience certain cases of the former and many of the latter, strongly accentuating the fact that such primary disease of the intestinal canal does exist. Then, again, one speaker was convinced that Koch's bacillus had little or nothing to do with the production of tubercular disease; but the contention had been met by so many accurate observations and experiments that he may be said to have been ruled out of court, though it was on all hands agreed that the bacillus might be helped in its work by various predisposing causes, many of which were brought into full prominence during the discussion. It was also accepted that the tuberculosis of cattle is similar, as regards its causal agent, to the tuberculosis of the human subject, and that the disease is merely apparently modified owing to the different conditions, and perhaps delicate tissue modifications, offered by the different hosts of the parasitic bacillus; and from the most careful and detailed experiments, of which a large number were described, there seems to be no question that tuberculosis is communicable from animals to man, and certainly there appears to be none that it is communicable in the opposite direction.

There was a general expression of opinion as the outcome of the discussion that legislation of some kind or other is necessary, but, as pointed out by Burdon Sanderson, if laws were made to-morrow there is absolutely no staff of inpectors capable of giving effect to any that might be drafted. It is probable that this will draw attention, first, to the necessity for conferring powers of inspection of dairy and store cattle on some central authority; and second, to the necessity there is that our veterinary surgeons should undergo a thorough scientific and practical training, such as would fit them to fill the posts from which unfortunately they are necessarily now in many instances excluded.

When all is said and done, it appears that the danger arising from the consumption of tuberculous meat is far less serious than that involved in the consumption of milk from tuberculous animals, as meat, if *thoroughly* cooked, appears to be perfectly innocuous, the tubercle bacilli being readily destroyed by heat, whilst the nutrient properties of the meat itself are little, if at all, interfered with by judicious cooking. In the case of milk, however, in which the presence of tubercle bacilli has been so often demonstrated, it has to be borne in mind that boiling so alters the constituents of the milk, especially the proteids, that it is rendered very much less digestible; and its nutritive value is greatly interfered with.

We now pass to the discussion.

TUBERCULOSIS IN ALL ITS RELATIONS.

Prof. Burdon Sanderson said the subject which he had undertaken to bring before the notice of the conjoint Sections for discussion was one of the gravest importance, for there was no disease, acute or chronic, which was so productive of human suffering or so destructive of human life. In a Congress of Hygiene the subject of tuberculosis could only be considered in relation to its causes, the aim of hygiene being to prevent disease, not to cure it. He wished specially to direct attention to those questions which relate to the dangers which are alleged to arise from the use of tuberculous food. (1) Does general tuberculosis in man originate from intestinal infection? (2) If it does, is it possible to guard against so fearful a danger? For the purpose of avoiding useless discussion on subjects on which there ought to be perfect agreement of opinion, he asked that certain fundamental propositions should be accepted as settled; such as, for example, the existence of a *materies morbi* in the form of the tubercle bacillus, its constant association with the tuberculous process, and the identity of human with bovine tubercle; and also that it be assumed that any part of the body of a tuberculous animal or any secretion of such an animal would, if it contained tubercle bacilli, be a source of danger, and that the use of such liquid or part ought to be prohibited or avoided. This being understood, we were in a position to enter on the questions which require answers, some of which are pathological or etiological, the others practical or administrative. The etiological questions might be said to relate to the three possible ways in which a human being may be infected by tubercle—namely, inheritance, pulmonary inhalation (atmospheric infection), and food (enteric infection). The practical issues were—

Digitized by Google

(1) Is the risk to the individual consumer of such a nature that it can be detected and estimated?

(2) Is it of such a nature that it can be counteracted?

(3) Is the collective risk to which the community is exposed sufficient to demand the interference of the State? and

(4) If it is, How can the State interfere with effect?

Of the two practical questions which relate respectively to infection by milk and to infection by meat, the latter was very largely discussed at a Congress on the subject of tuberculosis held in Paris in 1888, and has again been discussed very recently. In the first of these debates the medical profession did not take a very prominent part. The question whether the flesh of tuberculous animals is dangerous or not was regarded chiefly from the point of view of the veterinarian.

In 1888, M. Arloing, following out the principles enunciated by another gifted pathologist, the late M. Toussaint, that tubercle is a disease *totius substantiæ corporis*, maintained that the time had come to act "conformant à la logique." One out of every six carcasses had been shown, he said, to be infective, when tested by administering it to test animals as food. He calculated that over one thousand persons joined in the consumption of every such carcass, and consequently that one-sixth of this number—that is, about 170 persons—must be subjected to the risk of infection for every animal sent to the shambles. If this reasoning were true, if we could measure the danger to the human consumer by the presence of tuberculosis among animals used for food irrespectively of other considerations, then M. Arloing was right in his practical deduction from it that whatever interests conflict with public health they must give way. It was our duty to insist on the right of science to dictate; but in doing so it was necessary to be careful not to do so until the question had been looked at from all sides and the whole evidence had been heard.

In some of these discussions it had not been sufficiently considered that the question was not whether the consumption of tuberculous meat was in itself attended with risk, but whether the presence of tuberculous diseases among ourselves was in any way due to the fact that we occasionally eat meat which contained bacilli. It was not sufficient to show that on the one hand there was a fearful mortality from tuberculous diseases, and that on the other there existed a cause to which this calamity might be attributed. It must also be shown that the effect was actually produced by the cause, in such sense that if the cause were removed we might hope that the effect would disappear.

Twenty-three years ago Chauveau fed three heifers with tuberculous material from the body of a cow and obtained positive results. At that time the idea that tuberculosis was a virulent disease was new. M. Villemin had made his great discovery, but it had not yet been accepted, and consequently Chauveau's results were severely criticized, and were the subject of much discussion, which extended over several years (1868–74), during which he repeated his observations, effectually silenced his opponents, and determined with the greatest exactitude all the conditions which are required to insure success in the experimental production of tuberculosis by feeding. Gerlach about the same time made similar experiments in Germany which led him to advocate in the most energetic manner the restriction of the sale of tuberculous meat.

These two initial investigations were followed by many others. In 1884, Baumgarten showed that a couple of ounces of milk to which a pure culture of tubercle bacillus had been added were sufficient to produce characteristic tuberculosis in the intestines of a rabbit; and that the effect of such feeding was so constant that by examining the animals so fed at successive periods all the stages of the process could be thoroughly investigated, the most important result being that after a period of latency of a fortnight, during which no traces of infection were visible, the lymphatic follicles of the mucous membrane and the mesenteric glands began to enlarge simultaneously without any change whatever in the intestinal epithelium.

It was thus shown with a precision which was not before obtainable that the initial phenomenon of tuberculosis was primarily a proliferation of the adenoid tissue of the lymphatic system, and that the bacillus was capable of finding its way into the lymphatic system without leaving behind it any appreciable traces of its presence at the portals by which it had gained admission. Since 1884 our knowledge of the subject had been still further advanced by Cornil, under whose direction two very important researches, confirming and extending Baumgarten's results, have been recently published, from which it was evident that when the tubercle bacillus is absorbed from the intestine it follows the course of the lacteals, and that the lesions which it produces correspond closely with those which present themselves in those rare instances in which it is possible to observe the first beginnings of enteric tubercle in the human subject.

Much, however, has still to be learned by the experimental method—information which could only be gained by observations on animals. According to those who regard tuberculosis as necessarily a disease, *totius substantiæ corporis*, in which every part of the body is contaminated, all meat derived from the body of a tuberculous animal ought to be condemned, whether it appears healthy or not, for they argue that in every such animal, however localized the disease may be, bacilli circulate in the blood, and are so universally distributed.

Prof. Sanderson believed that this was not true, and that we are not entitled to assume that the flesh of every tuberculous animal is infectious unless it be proved to be so. As against the probability of its being so, it must be noted that the tuberculosis of cattle, although the product of the same bacillus as the tuberculosis of man, is a disease of comparatively slow progress. It localizes itself in structures which are not essential to life, and nutrition might be so little interfered with that the animal could be readily fattened for the market. There was no doubt that the flesh of such animals might be to all appearances in good condition, and might be offered for sale as meat of prime quality, and as yet we have no evidence that it is infective.

Turning from the source of infection to its effects, from the bacillus to its field of disease and death-producing action, Prof. Sanderson said that tuberculous diseases contribute something like 14 per cent. to the total of deaths from all causes, and that during childhood, as distinguished from adult life on the one hand and from infancy on the other, tuberculous mortality scarcely amounts to a quarter of this percentage, whereas in infancy it only falls a little short of it, and in early adult life, it very far exceeds it.

There was evidence that under certain conditions the virus of tubercle was absorbed by the lymphatic system from the small intestine in man, and that when this happens it may give rise to lesions of the same nature as those produced in animals by the injection of liquids in which bacilli are suspended—that is, to lesions which originate in the lymphatic system. Tuberculous disease of the intestinal mucous membrane, although very common, never occurred in the adult and very rarely in infancy as a primary disease. In the adult it might occur as an ulterior consequence of pulmonary consumption, the way in which it occurred being very evident. In the advanced stages of that disease muco-purulent liquid was discharged in quantity from the softened parts. This material charged with virulent bacilli might infect the mucous membrane along which it passed so that it is easy to distinguish bronchi which lead from vomicæ by the tuberculous nodules with which they are more or less beset. In advanced phthisis the sputum is so abundant that a certain proportion of it is from time to time swallowed. No effect is produced in the œsophagus or stomach, for along the former it passes too rapidly, while in the latter the mucous membrane is effectually protected by the gastric juice, which, although incapable of devitalizing the bacillus of tubercle, arrests its development. In the alkaline contents of the small intestine a condition more favourable to its development was found, and from there it was absorbed, just as any other particle of similar size might be, by the lymphatic follicles. Tuberculous disease of the small intestine in the adult thus occurred. It was always a secondary result of pulmonary phthsis.

In childhood the case is different. Tuberculosis does not begin to assert itself as a cause of death until the third month of extra uterine life, but after this there was good reason for supposing that the bacillus plays an important part as a cause of mortality.

To the pathologist the question of how latent tuberculosis of the lymphatic system or of bone originates, *i.e.* how the bacilli which produce them are introduced into the blood stream was one of great interest. Prof. Sanderson confessed it to be his belief that in a certain proportion of cases the cryptogenetic tuberculoses were due to causes which operate before birth. From Dr. Muller's Munich statistics it might be gathered that in less than half of the cases in which the lymphatic glands are found to be tuberculous the affection has its seat in the mesentery, and that the mucous membrane of the intestine is tuberculous in a still smaller proportion—less than a quarter. In many of these cases the mucous membrane was no doubt affected subse-

quently on tuberculous disease of the lungs, but in the remainder the disease seemed to be primary. If it could be proved that such cases were primary, the fact would afford clearer evidence than any we now possess of the enteric origin of tuberculosis.

In the absence of such proof, human pathology had very little indeed to say in favour of the belief that human tuberculosis could owe its origin to the consumption of tuberculous food, and even if it were proved that the absorbents afforded a channel of entry for the tuberculous virus in children it would have little significance as regards the consumption of meat.

The author held, therefore, that we are not as yet in a position to demand the interference of the State on the ground that the community actually suffers from the consumption of tuberculous meat, the evidence that it is so being too weak to be insisted on; but he maintained that the consumption of tuberculous meat was attended with some danger, and that on that ground its consumption ought to be prevented by the State and avoided by the individual.

As regards the administrative question, he held that if we had, to-morrow, a law forbidding the sale of any meat containing the bacillus of tubercle, it could not be carried out unless those charged with its administration were able to distinguish such contaminated meat from healthy meat, so that the efficiency of the law would depend on the question whether the art of discriminating between infecting and non-infecting meat had attained to such perfection as to enable an adequately trained inspector to exercise his function with effect. The practical result to which we have come was this. Everything must turn on diagnosis. The Legislature might direct that all meat intended for consumption should be subjected to inspection, might appoint inspectors, impose penalties, and provide just and adequate compensation, but all this would be of no use unless the principles on which the discrimination of infecting from non-infecting meat is to be founded could be laid down, and the services of skilled persons of sufficient intelligence to apply them could be secured. We might consider it quite certain that in this country at least it would at present be extremely difficult to find such persons. Not that the veterinarian was less capable than the doctor of making a scientific investigation, but that he does not possess, and has, as yet, had no opportunity of acquiring, the sort of skill which is necessary for making what the French call the *diagnose précoce* of tuberculosis. Two things in short are required, neither of which we have at our disposal—special scientific knowledge and technical skill, and the former of these must be acquired first. Science must determine, much more definitely than has been done as yet, what are the earliest changes which have their seat in the parts of animals used for food, and which of these might indicate danger to the consumer. This knowledge could only be acquired by experiments specially made for the purpose, and having been attained it could only be applied by technically trained persons. He illustrated the sort of skill required by comparing it to that possessed by the professional tea taster as regards the commercial value of tea. Why was the judgment of the expert reliable? Because he was responsible for it and was paid for it. It would be the same as regards the early recognition of tubercle in cattle, if skill and discrimination were paid for; and the same moment that this skill was required it would come into existence. What would be wanted in the inspector was not that he should be a pathologist or even a bacteriologist, but a trained expert; for although the rules unconsciously used by him might be based on scientific principles, it is not by these principles he is guided in each case, but by practical skill.

Dr. Sanderson then submitted the following propositions to the meeting of the combined Sections:—

(1) That tuberculosis must be added to the list of diseases regarded by the law as contagious. There is no sufficient reason for supposing that in the human adult the introduction of the bacilli of tubercle by enteric absorption is the efficient cause of tuberculosis. In infancy a large proportion of the apparently idiopathic tuberculous diseases of the lymphatic system are probably due to the penetration of bacilli into the organism from the intestine; but the evidence which we at present possess on this subject is not sufficiently precise or extended to serve as a basis for prophylactic action. For this reason the origin of tuberculosis in infancy is a subject which urgently requires investigation.

(2) It has been proved that the ingestion of any material which contains the bacilli of tubercle is a source of risk to the consumer, but the conditions which limit this risk are insufficiently known. It would, therefore, be unjust to enforce the destruction of any specimen of meat apparently healthy, even though it were known to be derived from a tuberculous animal, excepting on evidence given as regards the particular case that it would be infecting if administered to test animals.

(3) As regards the duty of the State in relation to the prevention of tuberculosis, what is immediately required is that an efficient system of skilled inspection should be created. This is desirable, not merely as a first step towards a prevention of the sale and consumption of tuberculous meat, but as an indispensable means of acquiring better information than now exists. To be of use it must be carried out on the principles I have already set forth. It must be conducted by men of technical skill acting under scientific guidance.

"In conclusion," said Dr. Sanderson, "I would beg you to notice that I have limited myself to the question of the consumption of meat. Although I have purposely left the milk question out of consideration, I have referred to facts which bear upon it. We have seen it to be exceedingly probable that about 40 per cent. of the children that die in hospital, die tuberculous. I have already expressed my belief that in some of these cases the disease is congenital—that is, dependent on causes which have operated before birth. Some are probably infected by inhalation of the tubercle bacillus from the atmosphere, notwithstanding that pathology affords so little evidence of it; but for the rest, notwithstanding the lack of satisfactory evidence, I cannot resist the conviction that the consumption of unboiled milk during the years which follow weaning must have its share in bringing about the fatal prevalence of tuberculous disease at that period of life. This being the case, I feel that, whatever course may be taken as regards meat, I can join heartily with those who think that the sale of contaminated milk ought to be put a stop to by all possible means, and I trust that on this subject there will be no difference of opinion, and that this Congress will take such action as may promote the progress of legislation."

Dr. Bang, Lecturer in the Royal Veterinary College, Copenhagen, in a paper on "The Alleged Danger of consuming the apparently Healthy Meat and Milk of Tuberculous Animals," stated that the great majority of investigators are agreed that the essential source of tuberculosis in man is found in man himself; but almost all admit that he may contract the disease through the ingestion of milk derived from animals affected with tuberculosis.

It is always agreed that such a danger exists, but as to the extent of the danger there is little unanimity.

Of course, it might be said that there would be no danger if the use of meat and milk from the tuberculous animals were entirely interdicted; but it must not be ignored that the application of such a stringent measure would entail enormous loss from an economical point of view, especially in those countries where the disease has a very wide distribution amongst bovine animals. He looked upon the general application of the French regulations as out of the question, at least for the present, whilst such a course appeared on the whole to be unnecessary. As regards milk, the question of prophylaxis was comparatively easily settled if it was resolved that it should never be employed without first being boiled. But then the question comes to be, How can we protect ourselves against the products of milk?

The experiments made by Galtier, the author, Hum, and others have proved that the various products derived from milk, butter, cream cheese, cheese, and butter-milk may all contain tubercle bacilli, and that these retain their vitality in such products for a period of from fourteen to thirty days. It was true the majority of these bacilli may be separated from milk if the cream be removed by means of a centrifugal machine, as is generally done in Denmark, but if the milk is very rich in bacilli a few usually remain in the milk, and even in the cream. In order to do away with this danger it is necessary to expose the milk or the cream before churning to a temperature high enough to kill the tubercle bacilli (85° C. for about five minutes); a temperature of from 60° to 75° C., however, being quite sufficient to attenuate the organic virus, so far as to render it incapable of setting up infection of the alimentary canal. This method is coming more and more into use in Denmark, as by it several other sources of infection in the butter are also neutralized. As, however, many people object to the taste of boiled milk, it became an important question to determine whether the milk of phthisical cows is really a source of danger in the majority of cases. He had determined

Digitized by Google

that when the udder is affected with tuberculosis there are usually numerous bacilli in the milk, which is consequently extremely dangerous. But he also finds that mammary tuberculosis is not so common as was at one time supposed. At the *abattoir* of Copenhagen, for example, it has been found that only in 1 per cent. of tuberculous cattle was there disease of the udder. From twenty-eight tuberculous cows, in which, however, there was no disease of the udder, the milk was injected into forty-eight rabbits, and in only two was there any positive result. He then inoculated forty guinea-pigs with milk from twenty-one tuberculous cows, in this case with four positive results. Recently he had carried on a new series of experiments with the milk from fourteen extremely phthisical cows. In this series the milk was virulent in three cases, so that from sixty-three tuberculous cows the milk contained virulent tubercle bacilli in nine cases only. All these cows were affected in a very high degree, and it is probable that in some at any rate the udder was affected; though this could not be demonstrated in the living animal, as it was in three out of the four cases of the second series. Others were affected with miliary tuberculosis in the different organs, a condition which one rarely finds in an animal that is still giving milk, and in one case the supra-mammary lymphatic glands were affected with tuberculosis, although no lesions in the udder itself could be demonstrated.

In several of the positive cases the number of bacilli in the milk must have been very small, as one only of the two guinea-pigs experimented upon succumbed to the disease, this happening in three instances.

It should be added that the quantity of milk injected in the later series was larger than in the earlier series. In the two first series 1 to 3 c.c. was injected, in the third 5 to 10 c.c. He maintained that, although in many cases the milk from phthisical cows is not virulent when the mammary gland is unaffected, it is in a certain proportion of cases, and should always be looked upon with suspicion, and that it is absolutely necessary to take prophylactic measures against the use of such milk, although the danger should no doubt not be exaggerated.

Meat.—Flesh itself very seldom contains any tubercle. Nevertheless it had been proved by a number of experiments that the muscle juice may contain tubercle bacilli, but such cases, according to the observations of Chauveau, of Arloing, Peuch, Galtier, Nocard, Kastner, and others, are absolutely in a minority. Amongst seventy-three phthisical cows these observers have found only ten in which the muscle juice gave evidence of virulence on injection into rabbits or guinea-pigs, and sometimes the juice inoculated only produced the disease in one of several animals inoculated.

M. Nocard's experiments in this connection are very interesting. He found that when a culture very rich in bacilli was injected into the vein of the ear of a rabbit, the muscle juice of the animal was virulent only when it was killed within five days after the inoculation, from which he argued that the bacilli carried by the vessels to the muscles only preserve their vitality for five days. If to this experimental result be added the observation that tubercle is very seldom developed in the muscles, even during the development of a condition of general tuberculosis, it must be concluded that muscular tissue is a soil so unfavourable for the growth of tubercle bacilli that they are not able to multiply. The number of bacilli, then, that can be found in the flesh of tuberculous animals is always extremely limited. It is of course true, as M. Arloing has objected to M. Nocard's conclusions, that the circulatory system of a tuberculous animal can continually receive into it fresh bacilli, and therefore until within only a few minutes before the animal is slaughtered. But, on the other hand, it must not be forgotten that it is only in the case of the development of an acute miliary tuberculosis that one can suppose that the number of bacilli introduced into the vessels can be considerable. In ordinary cases in which the tubercular process is developed slowly the bacilli would without doubt escape into the blood in very small quantities, and the number of bacilli that could be found at any given moment in the meat would be very small. Moreover, the experiments carried out by Galtier, Gebhardt, and others, render it very probable that the number of bacilli introduced into the alimentary canal, by which infection does not readily occur, plays a not unimportant part in the result obtained.

Prof. Bang stated that he had recently completed a series of experiments on the virulence of the blood of cows in an advanced stage of tuberculosis. From twenty tuberculous cows he inoculated thirty-eight rabbits and two guinea-pigs with defibrinated blood, injecting from 10 to 18 c.c. (in four cases only 5 to 9 c.c.). In eighteen cases the results were negative, in two positive, and one of these in which the lesion was small was one of two rabbits injected with blood from the same cow. The cow that supplied the blood with which the other positive result was obtained had developed acute miliary tuberculosis after an injection of tuberculin. Three weeks previously blood from the same cow had given negative results. Even amongst those cases in which the results were negative there were several cases of acute miliary tuberculosis.

He concluded from the foregoing that the seizure of all tuberculous animals is too stringent a measure. So long as the tuberculosis is strictly localized, the meat is not a source of danger; where the malady is generalized, the consumption of the meat may be dangerous, although it is not always so. The eating of uncooked meat should be discouraged, but the best means of avoiding danger to the health of man is to take all possible measures for preventing the propagation of tuberculosis amongst our domestic animals.

Prof. Arloing, of Lyons, contended that the question of transmissibility of tuberculosis from animals to man was one of very great importance, but he admitted that the *diagnose précoce* was very difficult. The danger to children of drinking milk from tuberculous cows was great, and he thought could scarcely be exaggerated. Moreover, he held very strongly that, except under certain special circumstances, the total condemnation of tuberculous meat was necessary, and on grounds of public health he dissented entirely from Dr. Bang's position.

The flesh of all tuberculous animals should be suspected as dangerous to health, the more so as meat was very often insufficiently cooked, the bacilli present under these conditions remaining pathogenic. From statistics he had gathered, he felt no doubt on this subject, and although it might be possible, by first carefully cooking under public supervision, to allow the flesh from animals in which the tuberculosis was localized to be sold, he still maintained his position that total confiscation of tuberculous meat was the safest method to be adopted. It was necessary, however, that in the first instance we should have a system of strict inspection, not only in our large towns, but also in all the smaller centres of population.

A paper was then given by Prof. M'Fadyean (Edinburgh and Dr. Woodhead (London), on the transmission of tuberculosis from animals to man, by means of flesh and milk derived from tuberculous animals. They maintained that the evidence as to the transmission through the flesh or milk of tuberculous animals was very conflicting, apparently in great part because the methods used were different, and the conditions were not uniform. They had attempted to follow the line of infection of tuberculosis in a number of children, and had found that in 127 cases analyzed tubercle of the intestine was present in 43; 24 of these cases occurring between one and five and a half years; tubercle of the mesenteric glands was found in 100 cases, or in nearly 79 per cent. of the whole; here, again, 62 of these occurring between one and five and a half years; and of 14 cases in which the mesenteric glands were primarily affected—*i.e.* no trace of tubercle could be found in any other part of the body—9 were referred to the same period. It was noticeable that of these 100 cases only 20 were diagnosed during life as suffering from abdominal tubercle. From all that could be learned from these cases (and reference could be made to a large number of other sets of statistics practically proving the same point), it was evident that intestinal and mesenteric tubercle are most frequently met with in children during the period after they are weaned, at which time cow's milk has been substituted for mother's milk. The point of entrance appeared in these cases to be by the intestine. They had come to the conclusion that in some cases at least the tubercle bacilli had passed from the intestine into the mesenteric glands without leaving any trace of lesion to indicate their point of entrance. There could now be no doubt that tubercle bacilli were sometimes present in the milk from tuberculous cattle, especially where the udder was affected, and they had been able to obtain such bacilli embedded in the epithelium of the milk ducts, or lying free in the ducts after the death of the animal. They concluded that wherever the presence of a tuberculous condition of the udder could be demonstrated clinically it would be little less than criminal to give the milk to delicate children, or even to children suffering from any catarrhal derangement of the intestine, a condition that is specially frequent amongst the

poor classes, where the standard of health is exceedingly low and the liability to catarrhal conditions very great. From a series of inoculations with tuberculous udder, and with milk from tuberculous udders, 14 out of 19, or over 70 per cent., had given positive results; with non-tubercular udders, and with milk from otherwise tuberculous cows, only 2 cases out of 13, or a little under 16 per cent., gave positive results. Where the failure to produce tuberculosis occurred in the first series, the number of bacilli was invariably small, and inoculations were usually into the subcutaneous tissue, though negative results were also obtained when other methods of infection were employed. They thought that in relation to the danger of taking tuberculous milk by the human subject, the site of the infection, and the relation of the number of bacilli introduced, played an important part in determining the severity and rapidity of the course of the disease, and they stated that their experience accorded with that of other observers, that inoculation into the peritoneal cavity is much more certain than inoculation into the subcutaneous tissue, especially where the number of bacilli introduced is comparatively small. They are also led to believe, from a number of feeding experiments, that the production of tuberculosis through the introduction of bacilli into the alimentary canal is of still less frequent occurrence than when inoculation is made into the connective tissue. As regards the possibility of the flesh of tuberculous animals setting up tuberculosis, (*a*) when introduced *en masse*, (*b*) when expressed juice only was exhibited, their experiments went to prove that the juice only did not in most cases contain a sufficient number of bacilli to set up tubercle, even when inoculated into small rodents, but from the fact that they have observed tubercular masses in the muscles of the buttock of tuberculous cattle, it must be accepted that tubercle bacilli may sometimes, though perhaps rarely, be present in considerable numbers in this position. Of three cows slaughtered in one day at one slaughter-house, well-defined tubercle was found in the muscles of the buttock of two animals; in one of these there was tuberculosis in every organ and part of the body; in the other there were only a few nodules and in some of the glands; there was certainly no pleural or peritoneal tubercle, and all the other organs were unaffected. They concluded that there was great necessity for a thorough inspection of both dairy cattle and of animals that were slaughtered for food purposes, but it might be accepted that the danger of contracting tubercle from milk was greater than that of contracting it from meat, and that only in a certain proportion of cattle affected with tuberculosis did there seem to be any danger to be anticipated from the ingestion of the flesh. In the main they agreed with Prof. Burdon Sanderson and Dr. Bang that there was not yet sufficient evidence on which to decide that the total seizure of meat from tuberculous animals should be resorted to.

Prof. Hamilton, of Aberdeen, said that there were two principal channels of infection, (1) the gastro-intestinal tract, (2) the lungs; but in addition to these we had what might be spoken of as localized tubercle, which seemed to be shut off entirely from all communication with the external world. (1) In the body the affection might take place by the air channels, as in the case of tubercular pneumonia, where the virus was probably inhaled and the air vesicles were the primary seat of infection. (2) By the blood vessels, as in cases of eruption of miliary tuberculosis. (3) By the lymphatic vessels, as in the more chronic forms of tuberculosis. In the gastro-intestinal canal a tubercular lesion might accompany an ordinary phthisis; it was often seen in children as a primary condition, and he should not be inclined to agree with Dr. Burdon Sanderson that it was not also primary in adults, as he himself had seen several cases, one quite recently. Previous catarrh was not always met with in the lung, but it was certainly a predisposing cause of tubercle, as it interfered with the protective epithelial covering. When tubercle followed whooping-cough, measles, and so on, it was probably the result of the spread of infection from pre-existing caseous spots, or it might be that the glands, weakened by the disease, fell an easy prey to the tubercle bacillus. He could not understand the comparative immunity from tubercle enjoyed by the pericardium and the stomach.

Prof. Nocard, of Paris, did not think that sufficient proof had as yet been accumulated that ingestion of tuberculous meat could give rise to tuberculosis in any large proportion of cases; the greater number of experimental cases had given negative results, and he should, to convince himself, require to see more positive results obtained in which all possible sources of failure could be eliminated. Whilst saying this, he must admit that in the case of children tuberculous material, whether in meat or milk, would always prove a very important source of danger. He would draw attention to the disease as it occurred in cats, on which animals he had made many experiments.

Dr. Hime, of Bradford, was glad to find that our foreign friends, who are not hampered as we are in making experiments, agree with us in the main. He thought that we were likely to run wild on the subject of the total seizure of tubercular meat, and he would point out that in no country does a total seizure law exist such as it is proposed to adopt here in England. In England he would point out that the inspection is worse than in any other country. He referred to Prof. Lingard's experiments given in an official report, which, he pointed out, spoke only of tubercle being transmitted by caseous material, and not by meat from a tuberculous cow, as was usually assumed. We had the authority of Koch himself, said Dr. Hime, that there is danger only when tubercular material itself is ingested. Infection by milk he looked upon as proved, but he would also insist very strongly that the majority of infection in cases of phthisis was directly between man and man, and it was far more important that we should eliminate possible sources of contagion between human subjects than that we should pay so much attention to the minor possibilities of infection from animals to man.

Dr. Barlow (London), speaking from a clinical point of view, was scarcely able to indorse the results of experimental researches, and he maintained that as regards tuberculosis in children we must for the present keep our minds open. There was no doubt that the *post-mortems* in children's hospitals gave evidence of the enormous frequency of tuberculosis, but the evidence that such disease was the result of the ingestion of milk and meat was comparatively slight. Other sanitary precautions, which he looked upon as of primary importance, must not be lost sight of in our discussion of the subject. He would, however, enter a protest against the use of the raw meat juice in the case of delicate children, as from what we had heard it was evident that such aliment might prove a source of considerable danger.

Prof. Perroncito, of Turin, referred to a number of experiments that he had carried out with meat, milk, and the products of the latter, and then pointed out that spontaneous tubercle very rarely occurred in the pig, though it might frequently be met with as the result of infection. The same might be said of sheep. Here, also, it might occur, though rarely, as the result of direct infection.

Prof. Burdon Sanderson, in reply, said he was pleased to find that the difference of opinion amongst so many authorities was so slight. It was evident that all were agreed that inspection was necessary, and there was also a general consensus of opinion as regards the difficulty of diagnosis. He was glad to find that although M. Arloing still retained his opinion as to the necessity for total seizure, except under very well-defined conditions, he had so far given way as to acknowledge that such meat might after careful cooking be retailed under special restrictions. In order that something definite might come out of this discussion, he proposed that it be minuted that "the etiology of tubercular disease of early infancy (between three months and five years)" be referred for discussion at the next Congress.

This was seconded by Dr. Septimus Gibbon, and was carried unanimously.

The President said that he had been greatly interested in the discussion, and he hoped that much good should arise therefrom. He was glad to find that there were some animals, such as the sheep and pig, in which spontaneous tubercle was never met with, and he hoped that we might eat these in safety. Sheep especially appeared to have a great immunity as regards tubercle, but pigs were not so safe, as they were apparently frequently the subject of tuberculosis.

Dr. Metschnikoff and Dr. Roux gave a joint paper on the changes that took place in the tissues around tubercle bacilli. It was read by the former, who illustrated his remarks by means of drawings on the black-board, and by microscopic specimens. They indicated the difference in the reaction of our tissues to the tubercle bacilli when the disease is going to run a favourable course, and when the animal is about to succumb rapidly to the disease. The process of recovery was indicated by the presence of concentric rings of hard and inflammatory tissue around the bacilli, which eventually lead to their absorption, the inflammatory tissue itself finally undergoing a process of calcification.

Digitized by Google

Prof. Ehrlich proceeded to give Koch's present views regarding tuberculin. He said that the results that had been obtained were exceedingly favourable, and most of those who had failed to obtain equally good results had failed because they had used too large doses of the remedy. The principle of cure rested in the local effects which tuberculin exercises on the specifically affected tissues; the inflammatory reaction passing to necrosis was neither desirable nor necessary, but, on the other hand, slight and even repeated stimuli would so act as to give rise to cicatrization of the tuberculous centres, so that the essence of this method of treatment was to retain as long as possible the specific excitation of the tissues, and not to do away with this, as was the case where large doses were used. Wherever successful results had been obtained they had all been by the use of repeated minute doses of tuberculin, which were only very gradually increased in strength, and it should be specially noted that the pathological signs found as the result of the action of tuberculin were always produced by large doses.

Prof. Cornil, Dr. Bardach, Dr. Ponfinck, and Prof. Hueppe were agreed that tuberculin was an heroic and dangerous remedy about which we as yet knew little, and which was therefore to be looked upon as still being experimented with. It also seemed to be the general opinion that where it was in use there existed a danger of setting up generalization of a tuberculosis that had hitherto been localized.

Dr. Hunter gave the results of his own experiments (described in the *British Medical Journal*), from which he had been able to show the nature of the active principle of tuberculin. He had succeeded in isolating principles quite different from those mentioned by Koch, or even reported by Dr. Ehrlich that morning as having been obtained by Koch. They were three—(1) those which produced fever, but set up no local reaction; (2) those which gave a local reaction, but no fever; and (3) those which set up neither fever nor local reaction, which had a distinctly remedial effect.

The President, summing up, hoped that in time we should all be able to obtain the wonderfully satisfactory results that had been so fully described by Prof. Ehrlich on Dr. Koch's behalf.

LETTERS TO THE EDITOR.

Rain-gauges.

I DO not think that valuable space in your columns should be occupied by rediscussing old questions. I do not wish to say a word in any respect discourteous to Mr. Fletcher, whose ability in other subjects has, I understand, been already recognized, but it really would have been better had he read up the subject before writing the remarkable letter which appears in NATURE of the 20th inst. (p. 371).

For experimental work, spherical, conical, inclined, horizontal, vertical, and tipping funnels have been used; but until the soil of the British Isles can be made to tilt in altitude and rotate in azimuth, so as to meet the path of falling rain, I think that we must adhere to gauges with horizontal mouths as the best representatives of the surface of the earth.

G. J. SYMONS.

British Association Reception Room, Cardiff, August 21.

Cloud Heights—Kinematic Method.

IN NATURE of April 16 (p. 563), and possibly elsewhere, I am made to speak of the method of determining the heights of clouds at sea used by Finemann and myself as the "aberration method." This was a misnomer that I supposed had been corrected. The more proper term is the "kinematic method," since in it we discuss the apparent motions of the clouds considered as the resultant of the true motions of the cloud and the observer. This is the term that I have used since May 1890, and would commend to others. CLEVELAND ABBE.

Weather Bureau, Department of Agriculture,
Washington, August 8.

THE BRITISH ASSOCIATION.

THE Cardiff meeting, if it was not made remarkable by any incident of very special importance, was, upon the whole, successful. Several of the addresses delivered by the Presidents of Sections were of exceptional interest, but some were very long, and we shall not be able to print all of them.

At the first meeting of the General Committee, held on Wednesday, August 19, the report of the Council for 1890–91 was read by Sir Douglas Galton. Dr. Gladstone moved a vote of thanks to Prof. Williamson for his long and valuable services as general treasurer, paying a tribute to the manner in which that gentleman had fulfilled his duties. Sir Douglas Galton seconded, and the resolution was cordially agreed to. Mr. Vernon Harcourt moved, and Sir J. Douglass seconded, the appointment of Prof. Arthur Rücker as general treasurer. This motion was also agreed to. At the meeting of the General Committee on Monday, a deputation from Nottingham was introduced. The Association was invited by the Mayor and town authorities to visit Nottingham in 1893. It was stated that it was twenty-five years since the Association had visited Nottingham. The invitation was accepted on the motion of Mr. Preece. It was also unanimously agreed, on the motion of Canon Tristram, to elect Sir A. Geikie as President of the Association, which meets at Edinburgh next year. The Lord Provost of Edinburgh, the Marquis of Lothian, the Earl of Rosebery, Lord Kingsburgh, Principal Sir William Muir, Prof. Sir Douglas Maclagan, Sir William Turner, Prof. Tait, and Prof. Crum Brown were elected Vice-Presidents for the Edinburgh meeting. Prof. G. F. Armstrong, Principal F. Grant Ogilvie, and Mr. John Harrison were elected Local Secretaries for the meeting at Edinburgh, and Mr. A. Gillies Smith Local Treasurer. A deputation from Edinburgh also attended with reference to the fixing of a date for the Edinburgh meeting. It was stated on behalf of the Town Council that September 28 was favoured as the opening date of the meeting, though August 3 and September 21 were also mentioned as alternative dates. A motion was made to fix August 3, while an amendment was moved for September 12; but as only thirteen voted for the amendment, the original motion was agreed to—that is, the Association will meet at Edinburgh next year on August 3. The general officers were re-elected, and the following gentlemen were elected Members of Council for the ensuing year:—Dr. W. Anderson, Prof. Ayrton, Sir B. Baker, Mr. H. W. Bates, Prof. Darwin, Sir J. N. Douglass, Prof. Edgeworth, Dr. J. Evans, Prof. Fitzgerald, Sir Archibald Geikie, Mr. R. T. Glazebrook, Profs. J. W. Judd, Liveing, Lodge, Mr. W. H. Preece, Profs. W. Ramsay, Reinold, Roberts-Austen, Schäfer, Schuster, Sidgwick, Mr. G. J. Symons, Profs. T. E. Thorpe, Marshall Ward, Mr. W. Whitaker, Dr. H. Woodward. The following impressions have been recorded by a correspondent:—

CARDIFF, *Tuesday Evening.*

One of the most prominent features of the Cardiff meeting has undoubtedly been the prevailing bad weather. Rain and cold have had their usual depressing results, and may to some extent account for the disappointment which exists among many of those in attendance. The Local Committee have done their best to render the meeting a social success, but the entertainments by the Municipality and the citizens of Cardiff have been of a somewhat restricted character. Notwithstanding the unpromising state of the weather, the excursions on Saturday and Sunday were largely taken advantage of, and the reception given by Lord Windsor on the latter day was specially appreciated. The total attendance has been about 1500, within 200 of the Leeds meeting, while the amount of money available for grants is within a few pounds of last year. Naturally there has

Digitized by Google

been considerable talk with reference to the address of the President of Section A, and opinion is divided as to the propriety of introducing the metaphysical into a Section which has emphatically to do with the "solid ground of Nature." On the other hand, Prof. Lodge's experiment to test whether the ether is disturbed in the presence of a rapidly-moving body has excited the greatest interest and admiration.

The *soirées* at the present meeting can hardly be compared in attractiveness and brilliancy with those held last year in Leeds. Wealthy and populous as Cardiff is, she has not command, apparently, of the scientific and artistic collections which are so creditable to the intelligence and taste of the dingy Yorkshire city. However, the dance into which to-night's *conversasione* developed evidently atoned for a multitude of shortcomings. The lectures have been fairly well attended, Prof. Rücker's beautiful experiments evidently fascinating his audience, in spite of a serious hitch caused by the failure of a steam-engine to do its duty when called upon. The discussion, in Section D, as to the relations between animal and plant life was well sustained, and it is a pity that arrangements had not been made to have it fully reported. This can be done at very small cost, and the publication of detailed reports of such discussions could not but greatly increase the good they are calculated to do. There is a general belief that inter-Sectional discussions would be of immense advantage in showing the intimate relations which exist between the different branches of science, and in stimulating research in profitable directions. It is probable that several such discussions may be arranged for the next meeting.

As usual, Section E had its sensation. A very large audience attended to hear Mrs. French Sheldon describe her journey to Lake Chala, at the base of Kilimanjaro. Mrs. Sheldon was evidently suffering greatly from her serious accident; and although her address was somewhat disjointed, it contained a good deal of fresh information, especially on the natives, which male travellers have hitherto overlooked. Mrs. Bishop (Miss Isabella L. Bird) proved equally attractive in describing her visit to the Bakhtiari country and the Karun River, and, as might have been expected, was somewhat more solid than her less-experienced fellow traveller.

The Ordnance Survey formed the subject of an important discussion in Section E, and the Association as a body has resolved to do its utmost to induce Government to introduce reforms. It is fortunate that by the combined action of Sections A, E, and G, a grant of £75 has been obtained for supplying instruments for climatological observations in Central Africa.

There was considerable discussion at the general committee meeting yesterday as to the date of the Edinburgh meeting next year. In certain quarters the end of September was advocated, but there can be no doubt that the great majority of the working members of the Association preferred the beginning of August, a date which will suit those connected with the Universities and will catch the citizens of Edinburgh before they leave for their holidays. It is, therefore, not surprising that August 3 has been fixed upon for the Edinburgh meeting, the President of which will be Sir Archibald Geikie. Nottingham has been selected as the place of meeting for 1893.

It is evident that the people of Cardiff are somewhat at a loss what to make of the Association and of the hundreds who are crowding the streets of the town and rushing from one Section room to another. The Sectional secretaries especially, seem to be a puzzle. In the hotel in which they are housed a commercial stock-room has been set apart for their use, with a long baize-covered table down the centre; while to discourage all tendencies to loafing, they have been provided with nothing else but hard kitchen chairs to sit upon.

Altogether, from a scientific point of view, the Cardiff meeting may be said to have come up to a fair average.

SECTION B.

CHEMISTRY.

OPENING ADDRESS BY PROF. W. C. ROBERTS-AUSTEN, C.B., F.R.S., PRESIDENT OF THE SECTION.

THE selection of Cardiff as a place of meeting of the British Association led to the presidency of Section B being intrusted to a metallurgist. It will be well, therefore, to deal in this address mainly with considerations connected with the subject to which my life has been devoted, and I hope that it may be possible for me to show that this practical art has both promoted the advancement of science and has received splendid gifts in return.

It is an art for which in this country we have traditional love; nevertheless the modes of teaching it, and its influence on science, are but imperfectly understood and appreciated. Practical metallurgists are far too apt to think that improvements in their processes are mainly the result of their own experience and observation, unaided by pure science. On the other hand, those who teach metallurgy often forget that for the present they have not only to give instruction in the method of conducting technical operations, but have truly to educate, by teaching the chemistry of high temperatures, at which ordinary reactions are modified or even reversed, while they have further to deal with many phenomena of much importance, which cannot, as yet, be traced to the action of elements in fixed atomic proportions, or in which the direct influence of the atom is only beginning to be recognized.

The development of a particular art, like that of an organism, proceeds from its internal activity; it is work which promotes its growth and not the external influence of the environment. In the early stage of the development of an industry the craftsmen gather a store of facts which afford a basis for the labours of the investigator, who penetrates the circle of the "mystery" and renders knowledge scientific. Browning, inspired by the labours of a chemist, finely tells us in his "Paracelsus":—

> To know
> Rather consists in opening out a way
> Whence the imprisoned splendour may escape,
> Than in effecting entry for a light
> Supposed to be without.

If it be asked who did most in gaining the industrial treasure and in revealing the light of chemical knowledge, the answer is certainly the metallurgists, whose labours in this respect differ materially from others which have ministered to the welfare of mankind. First it may be urged that in no other art have the relations between theory and practice been so close and enduring. Bacon, who never undervalued research, tells us that in the division of the labour of investigation in the New Atlantis there are some "that raise the former discoveries by experiment into greater observations, axioms, and aphorisms: these we call the *interpreters of nature.*" There are also others "that bend themselves, looking into the experiments of their fellows and casting about how to draw out of them things of use and practice for man's life and knowledge: . . . these we call the *dowry men or benefactors.*" In reviewing the history of metallurgy, especially in our islands, it would seem that the two classes of workers, the interpreters of nature and the practical men, have for centuries sat in joint committee, and, by bringing theoretical speculation into close connection with hard industrial facts, have "carried us nearer the essence of truth."

The main theme of this address will therefore be the relation between theory and practice in metallurgy with special reference to the indebtedness of the practical man to the scientific investigator.

We will then consider—

(1) Certain facts connected with "oxidation" and "reduction," upon which depend operations of special importance to the metallurgist.

(2) The influence in metallurgical practice of reactions which are either limited or reversible.

(3) The means by which progress in the metallurgic art may be effected, and the special need for studying the molecular constitution of metals and alloys.

(1) The present year is a memorable one for chemists, being the centenary of the birth of Faraday and the bi-centenary of the death of Robert Boyle. The work of the former has recently been lovingly and fittingly dealt with in the Royal Institution, where he laboured so long. I would, in turn, briefly

Digitized by Google

recall the services of Boyle, not, however, on account of the coincidence of date, but because with him a new era in chemistry began. He knew too much about the marvellous action of "traces" of elements on masses of metal to feel justified in pronouncing absolutely against the possibilities of transmutation, but he did splendid service by sweeping away the firm belief that metals consist of sulphur, salt, and mercury, and by giving us the definition of an element. He recognized the preponderating influence of metallurgy in the early history of science, and quaintly tells us that "those addicted to chemistry have scarce any views but to the preparation of medicines or to the improvement of metals," a statement which was perfectly correct, for chemistry was built up on a therapeutic as well as a metallurgic basis. The fact is, however, that neither the preparation of materials to be employed in healing, nor the study of their action, had anything like the influence on the growth of theoretical chemistry which was exerted by a few simple metallurgical processes. Again, strange as it may seem, theoretical chemistry was more directly advanced by observations made in connection with methods of purifying the precious metals, and by the recognition of the quantitative significance of the results, than by the acquisition of facts incidentally gathered in the search for a transmuting agent. The belief that chemistry "grew out of alchemy" nevertheless prevails, and has found expression in this Section of the British Association. As a fact, however, the great metallurgists treated the search for a transmuting agent with contempt, and taught the necessity of investigation for its own sake. George Agricola, the most distinguished of the sixteenth century metallurgists, in his work "De Ortu et Causis Subterraneorum" (lib. v.), written about the year 1539, disdainfully rejects both the view of the alchemists that metals consist of sulphur and mercury, and their pretended ability to change silver into gold by the addition of foreign matter.

Biringuccio (1540) says, "I am one of those who ignore the art of the alchemists entirely. They mock nature when they say that with their medicines they correct its defects, and render imperfect metals perfect." "The art," he adds, "was not worthy of the consideration of the wise ancients who strove to obtain possible things." In his time, reaction between elements meant their destruction and reconstitution; nevertheless, his sentence "transmutation is impossible, because in order to transmute a body you must begin by destroying it altogether," suggests that he realized the great principle of the conservation of mass upon which the science of chemistry is based. We have also the testimony of the German metallurgist, Becher, who improved our tin-smelting in Cornwall. He is said to have caused a medal to be struck in 1675, which bore the legend, "Hanc unciam argenti finissimi ex plumbo arte alchymica transmutavi," though he should have been aware that he had only extracted the precious metal from the lead, and had not transmuted the base one. This is a lapse which must be forgiven him, for his *terra pinguis* was the basis of the theory of phlogiston, which exerted so profound an influence for a century after his death, and he wrote, "I wist that I have got hold of my pitcher by the right handle, for the pseudo-chemists seek gold, but I have the true philosophy, science, which is more precious."

At this critical period what was Boyle doing when the theory of phlogiston dawned in the mind of the metallurgist Becher? In 1672 Boyle wrote his paper on "Fire and Flame weighed in the Balance," and came to the conclusion that the "ponderous parts of flame" could pass through glass to get at melted lead contained in a closed vessel. It has been considered strange that he did not interpret the experiment correctly, but he, like the phlogistic chemists, tried to show that the *subtilis ignis*, the material of fire or phlogiston, would penetrate all things, and could be gained or lost by them. Moreover, his later experiments showed him that glass was powerless to screen iron from the "effluvium of a loadstone." His experiment with lead heated in a closed glass vessel was a fundamental one, to which his mind would naturally revert if he could come back now and review the present state of our knowledge in the light of the investigations which have been made in the two centuries that have passed since his own work ceased. If he turned to the end of the first century after his death he would see that the failure to appreciate the work of predecessors was as prevalent in the eighteenth century as in the sixteenth. The spirit of intolerance which lead Paracelsus to publicly burn, in his inaugural lecture at Basle, the works of Galen, Hippocrates, and Avicenna, survived in the eighteenth century, when Madame Lavoisier burnt the works of Stahl, but it was reserved for the nineteenth century to reverently gather the ashes, recognizing that when the writers of the school of Becher spoke of phlogiston they meant what we understand by potential energy.

If Boyle, finding that the Fellows of the Royal Society had not carried out their intention to build a "Repository and Laboratory," sought the School of Mines and came to the Royal College of Science, he would surely thank my colleague, Prof. Thorpe, for his vigorous defence last year, as President of this Section, of the originality of the work of Priestley and Cavendish, to which Boyle's own researches had directly led. We on our part, remembering Berzelius's view that "oxygen is the centre point round which chemistry revolves," would hope to interest him most by selecting the experiments which arose out of the old metallurgical operation of separating the precious metals from lead by "cupellation." When, in conducting this operation, lead is heated in the presence of air, it becomes converted into a very fluid dross. Boyle had, in 1661, taken this operation as the very first illustration in his "Sceptical Chemist" in proof of his argument as to the elemental nature of metals. He would remember the quantitative work of Geber in the eighth century, who stated that the lead so heated in air acquired a "new weight," and he would appreciate the constant reference to the operation of cupellation from the close of the sixth century B.C., when the prophet Jeremiah wrote, to the work of Jean Rey in 1629, whose conclusions he would wish he had examined more closely. Lord Brouncker, as first President of the Royal Society, had called attention to the increase in weight of the lead in the "coppels" in the Assay Office in the Mint in the Tower, and Mayo had shown that the increase in weight comes from a distinct "*spiritus*" in the air. Boyle would incidentally see that Newton had accepted office in the Mint, where he doubtless continued his experiments on calcination, begun some time before, and, as if to mark his interest in the operation of assaying, figures are represented on a bas-relief on his tomb in Westminster Abbey as conducting cupellation in a muffle. The old work merges wonderfully into the new. Chevreul, in the nineteenth century, confirms Otto Tachens's view in the seventeenth, as to the saponifying action of litharge. Deville employs molten litharge to absorb oxygen dissociated from its compounds, and Graham, by extracting occluded gases from iron and other metals, proves the accuracy of the old belief that elastic fluids can freely permeate even solid metals.

We may imagine with what vivid interest Boyle would turn, not merely to the results of Priestley's work, but to his methods. Priestley had decomposed litharge with the electric spark, and had satisfied himself in 1774 by heating red lead that the gas he obtained in his earlier experiments was really the one now called oxygen.

Boyle would see, that in the period 1774–77 Lavoisier, being attracted by the "sceptical chemist's" own experiment on the heating of lead in closed vessels, overthrew the phlogistic theory, and placed chemistry on a firm basis by showing that the increase in weight of lead and tin, when heated in air, represents exactly the weight of the gaseous body added; and, finally, Dalton having developed the atomic theory and applied it to chemistry, Berzelius made lead memorable by selecting it for the first determination of an atomic weight.

Without diverting his attention from the phenomena of oxidation, Boyle would find questions the interest of which is only equalled by their present obscurity. He would contemplate the most interesting phase of the history of chemical science, described by Van 't Hoff as that of its evolution from the descriptive to the rational period, in the early days of which the impossibility of separating physics and chemistry became evident, and Boyle would find that chemistry is now regarded from the point of view of the mechanics of the atoms.

Deville's experiments on dissociation have rendered it possible to extend to the groups of atoms in chemical systems the laws which govern the fusion and vaporization of masses of matter, and this has produced a revolution comparable in its importance to that which followed the discovery of the law of definite proportions, for dissociation has shown us that true causes of chemical change are variations of pressure and of temperature. For instance, oxygen may be prepared on an industrial scale from air by the intervention of oxide of barium heated to a constant temperature of 700°, provided air be admitted to the heated oxide of barium, under a pressure of 1½ atmospheres, while the oxygen, thus absorbed, is evolved if the containing vessel be rendered partially vacuous. It will be evident, therefore, that

Digitized by Google

at a certain critical temperature and pressure the slightest variation of either will destroy the equilibrium of the system and induce chemical change.

The aim of Boyle's chemical writings was to show that no barrier exists between physics and chemistry, and to "serve the commonwealth of learning by begetting a good understanding betwixt the chemists and the mechanical philosophers," who had, as he said, "been too great strangers to each other's discoveries." In view of the dominant lines of research which occupy chemists at the present time, such, for instance, as the investigations of "osmotic pressure" and of the application of Boyle's own law to salts in solution, he would feel that his hope had been realized, and that, though he lived a century too soon to take part in Berthollet's discussion with Proust, he nevertheless shares Berthollet's triumph in the long-delayed but now rapid development of chemistry as a branch of applied mechanics.

We need, however, no longer look at these questions from the point of view of Boyle, for our own interest in the application of chemical mechanics to metallurgy is sufficiently vivid, as instances to be given subsequently will show.

Hitherto I have mainly dwelt on questions relating to oxidation, but not less interesting is the history of the steps by which an accurate knowledge was acquired of the other great process practised by the metallurgist, the one to which Paracelsus was the first to apply the name of "reduction." Its explanation followed naturally from the elucidation of the phenomena of combustion by Lavoisier, who in continuation of Macquer's experiments of 1771 proved, in conjunction with other workers, that carbonic anhydride is produced when the diamond is burnt in air or oxygen. Carbon has been known for ages as the most important of the reducing agents, but when, in 1772, Lavoisier heated oxide of lead and carbon together, he did not at first recognize that carbonic anhydride had been produced, simply because the volume of the gas set free was the same as if oxygen merely had been liberated. He soon, however, saw that neither the carbon alone, nor the oxide of lead alone, gave rise to the evolution of carbonic anhydride, which resulted from the *mutual action* of carbon and a constituent of the litharge. "This last observation leads us insensibly," he adds, "to very important reflections on the use of carbon in the reduction of metals." It most certainly did, and by 1815 an accurate, if incomplete, view of reduction had passed into the encyclopædias. It was seen that the removal of oxygen from burnt metals, by carbon, "gives the metals," as Fourcroy and Vauquelin put it, "a new existence." Some ten years later Le Play attempted to show that reduction is always effected by the intervention of carbonic oxide, which elicited the classical rejoinder from Gay-Lussac, who pointed out that "carbon alone, and at very moderate temperatures, will reduce certain metallic oxides without the intervention of carbonic oxide or of any other elastic fluid." I mention these facts because metallurgists are slow to recognize their indebtedness to investigators, and too often ignore the extreme pains with which an accurate knowledge has been acquired of the principles upon which their processes have been based.

The importance of a coherent explanation of reduction in smelting pig-iron is enormous. The largest blast-furnaces in 1815 hardly exceeded those in use in the previous century, and were at most only 40 feet high, with a capacity of 5000 cubic feet. At the present day their gigantic successors are sometimes 90 feet high, with a capacity of 25,000 cubic feet. This development of the blast-furnace is due to the researches of a number of investigators, among whom von Tunner, Lowthian Bell, and Grüner deserve special mention. We are, however, forcibly reminded of the present incompleteness of our knowledge of the mechanism of reduction, when we remember that the experiments of H. P. Baker have led us to believe that pure carbon cannot be burnt in perfectly dry and pure oxygen, and therefore that the reducing agent, carbonic oxide, cannot be produced at all unless moisture be present.

Ludwig Mond, Langer, and Quincke, teach us not only that nickel can separate carbon from carbonic oxide, but the wholly unexpected fact that dry carbonic oxide can at a temperature of 100° take up nickel, which it again deposits if heated to 150°. Mond and Quincke, and, independently, Berthelot, have since proved the existence of the corresponding compound of iron and carbonic oxide, and it may safely be concluded that in the blast-furnace smelting iron this peculiar action of carbonic oxide plays an important part, and it doubtless aids the carburization of iron by cementation. It is truly remarkable that the past year should have brought us so great an increase in our knowledge of what takes place in the reduction of an oxide of iron, and in the carburization of the liberated metal. My own experiments have, I trust, made it clear that iron can, at an elevated temperature, be carburized by the diamond *in vacuo*; that is, in the absence of anything more than "a trace" of an elastic fluid or of any third element. Osmond has further shown within the last few months that the action between iron and carbon is a mutual one, for though carbon in the pure diamond form carburizes iron, the metal in its turn, at a temperature of 1050°, attacks the diamond, invests it with a black layer, and truly unites with it.

The question of the direct carburization of iron (Darby's process) by filtering the molten metal through carbon, promises to be of much importance, for at present, as is well known, two millions of tons of steel which are made in the Bessemer converter in this country alone, are re-carburized after "the blow" by the addition of spiegeleisen.

Carbonic oxide, moreover, would appear to be more chemically active than had been supposed; for during the present year Berthelot has shown that the perfectly pure gas heated to 500° or 550° produces carbonic anhydride with the deposition of carbon at red heat, not by ordinary dissociation, but by decomposition preceded by polymerization. He further shows that carbonic oxide will decompose ammoniacal nitrate of silver, and thus brings it into close connection with the aldehydes.

(2) In turning to the modern aspects of metallurgical practice, we shall see that the whole range of the metallurgist's field of study is changing. It is no longer possible for him to devise a series of operations on the evidence afforded by a set of equations which indicate the completion of an operation; he has, as I have already suggested, to consider the complicated problems which have been introduced into chemistry from the sciences of physics and mechanics. He has, in fact, no longer to deal merely with atoms and molecules, but with the influence of mass. As Ostwald points out, we are reminded that many chemical processes are reciprocating so that the original products may be obtained from the product of the reaction. The result of such opposed processes is a state of CHEMICAL EQUILIBRIUM, in which both the original and the newly-formed substances are present in definite quantities that remain the same so long as the conditions, more especially temperature and pressure, do not undergo further change. Again, in very many metallurgical processes, reactions are rendered incomplete by the limitations imposed by the presence of bodies which cannot be speedily eliminated from the system, and the result may be to greatly retard the completion of an operation. The time has come when the principles of dynamic chemistry must be applied to the study of metallurgical problems if they are to be correctly understood, and it is, moreover, necessary to remember the part played by the surface separating the different aggregates in contact with one another. When, for instance, a reaction has to take place accompanied by the evolution of gas, there must be space into which the gas can pass. The rate, therefore, at which change takes place will obviously depend on the state of division of the mass.

One of the most remarkable points in the whole range of chemistry is the action engendered between two elements capable of reacting by the presence of a third body. It may be, and this is the most wonderful fact of all, that merely a trace of a third body is necessary to induce reaction, or to profoundly modify the structure of a metal. H. Le Chatelier and Mouret have pointed out that in certain cases it is inaccurate to say that the third body causes the reaction to take place, because, after it has destroyed the inter-molecular resistances which prevented the reaction taking place, the third body ceases to intervene. This is apparently the case when platinum sponge effects the union of oxygen and hydrogen, or, conversely, when very hot platinum splits up water vapour into its constituent gases. Future investigation will, it is to be hoped, show whether the platinum does not exert some direct action in both cases. We can no longer neglect the study of such questions from the point of view of their practical application. The manufacture of red lead presents a case in point. In "drossing" molten lead, the oxidation of the lead is greatly promoted by the presence of a trace of antimony; and conversely, in the separation of silver from molten lead, by the aid of zinc, H. Roessler and Endelmann have recently shown that aluminium has a remarkable effect in protecting the zinc from loss by oxidation, and further, the presence of one-thousandth part of aluminium in

Digitized by Google

the zinc is sufficient to exert this protecting action on that metal. I am satisfied that if our metallurgists are to advance their industrial practice, they must, if I may use such an expression, persistently think in calories, and not merely employ the ordinary atomic "tools of thought." They will then be able to state what reactions can, under given conditions, take place; to indicate those which will be completed; and to avoid those that are impracticable.

In France, the country of so many great metallurgists, men like Le Chatelier and Ditte are doing admirable service, by bringing the results of the labours and teaching of St. Claire Deville within the range of practical men. And if I do not refer more specifically to their work it is for want of space and not of appreciation, but a few simple cases of reversible actions will perhaps make the subject clear. In the blast-furnace the main reducing agent, carbonic oxide, is produced from the solid fuel by the reaction $CO_2 + C = 2CO$, a reaction which is theoretically impossible because it is endothermic, and would be attended by absorption of heat. But heat external to the system intervenes, and acts either by depolymerizing the carbon into a simpler form which can combine with oxygen of the CO_2 with evolution of heat, or by dissociating carbonic anhydride sets oxygen free which combines with the carbon. Reduction of oxide of iron in the blast-furnace is mainly effected by carbonic oxide according to the well-known reaction

$$Fe_2O_3 + 3CO = 2Fe + 3CO_2.$$

But the gas issuing from a blast-furnace contains carbonic oxide, an important source of heat. The view that this loss of carbonic oxide was due to the fact that the contact of the ore and the reducing gas was not sufficiently prolonged, led to a great increase in the height of blast-furnaces, but without, as Grüner showed, diminishing the proportion of carbonic oxide escaping from the throat. The reduction of an iron ore by carbonic oxide only takes place within certain well-defined limits, and a knowledge of the laws of chemical equilibrium would have saved thousands and thousands of pounds which have been wasted in building unduly high furnaces. I would add that large sums have also been sacrificed in the vain attempt to smelt oxide of zinc in the blast-furnace, for which operation patents have frequently been sought, in ignorance or defiance of the readiness with which the inverse action occurs, so that the reducing action of carbon on oxide of zinc may be balanced by the re-oxidation of the reduced zinc by carbonic anhydride, which is the product of the reduction. A further instance may be borrowed from an electro-chemical process which has been adopted for obtaining alloys of aluminium. As is well known, all attempts to effect the direct reduction of alumina by carbon have failed, because the reaction

$$2(Al_2O_3) + 3C = 4Al + 3CO_2$$

requires 783·2 calories, while only 291 calories would result from the conversion of carbon into carbonic anhydride, therefore the reaction cannot be effected; but in Cowles's process aluminium is nevertheless liberated when alumina is mixed with charcoal and strongly heated by the passage of an electric current. This result is due, not to a simple reduction of alumina, but to its dissociation at the high temperature produced by the passage of a current of 1600 amperes between carbon poles, the liberated aluminium being at once removed from the system by metallic copper, which is simultaneously present and may not be without action itself.

An instance of the importance of these considerations is presented in the manufacture of steel by the basic process. Much care is devoted to obtaining conditions which will insure, not only the elimination, but the order of the disappearance of the impurities from the molten pig-iron. In the basic process as conducted in the closed converter, the phosphorus does not disappear until the carbon has left the fluid bath, whilst, when the open-hearth furnace is used, the elimination of the phosphorus may be effected before that of the carbon, and it is asserted that, if the carbon goes before the phosphorus is got rid of, a further addition of carbon is necessary. A curious and subtle case of chemical equilibrium is here presented. In the open-hearth furnace and Bessemer converter respectively, the temperatures and pressures are different, and the conditions as to the presentation of oxygen to the fluid bath are not the same. The result is that the relative rates of oxidation of the phosphorus and carbon are different in the two cases, although in either case, with a given method of working, there must be a ratio between the phosphorus and carbon in which they disappear simultaneously. The industrial bearing of the question is very remarkable. In the basic Bessemer process the tendency of the phosphorus to linger in the bath renders an "after-blow" necessary; it may be only of a few seconds' duration, but much iron is nevertheless burnt and wasted, and Mr. Gilchrist tells me that, if this after-blow could be avoided, a saving of some 6 per cent. of the yield of steel would be effected annually, the value of which, at the present rate of output and price of steel, is no less than a quarter of a million sterling.

The volatilization of sulphur in the converter while it is retained by the steel in the open-hearth furnace, and the increase in the percentage of manganese which leaves the slag and returns to the bath of metal in the converter at the end of the "blow," will probably be traced to the disturbance of equilibrium which attends very slight variations in the conditions, especially as regards temperature and pressure, under which the operations are conducted.

In the blast-furnace the reducing action must be greatly dependent on the rate at which alkaline cyanides are formed, and Hempel has recently shown, by the aid of well-devised experiments, that the quantity of cyanides which may be obtained at a high temperature from carbon, nitrogen, and alkaline oxides, increases as the pressure becomes greater.

Metallurgical chemistry is, in fact, a special branch of chemical science which does not come within the ordinary sphere of the academic teaching of chemistry. It is often urged that metallurgical practice depends upon the application of chemical principles which are well taught in every large centre of instruction in this country, but a long series of chemical reactions exist which are of vital importance to the metallurgist, though they are not set forth in any British manual of chemistry, nor are dealt with in courses of purely chemical lectures. I feel bound to insist upon this point, because, as Examiner in Metallurgy for the Science and Art Department, I find that purely analytical and laboratory methods are so often given in the belief that they are applicable to processes conducted on a large scale, and at high temperatures.

We are told that technical instruction should be kept apart from scientific education, which consists in preparing the student to apply the results of past experience in dealing with entirely new sets of conditions, but it can be shown that there is a whole side of metallurgical teaching which is truly educational, and leads students to acquire the habit of scientific thought as surely as the investigation of any other branch of knowledge.

It is, in fact, hardly possible in a course of theoretical chemistry to devote much attention to specific cases of industrial practice in which reactions are incomplete, because they are limited by the presence of bodies that cannot be directly eliminated from the chemical system. Take, for instance, the long series of reactions studied by Plattner, who published the results of his investigations in his celebrated treatise, "Die Metallurgische Röstprozesse," Freiberg, 1856, whose work I have chosen as a starting-point on account of our presence in South Wales near the great copper-smelting district of Swansea. A complex sulphide, of which copper is the main metallic constituent, contains some fifty ounces of silver to the ton. The problem may be supposed for the present to be limited to the extraction of the precious metal from the mass in which it is hidden, and the student deriving his knowledge from an excellent modern chemical treatise would find the case thus stated:—

"Ziervogel's process depends upon the fact that when argentiferous copper pyrites is roasted, the copper and iron sulphides are converted into insoluble oxides, whilst the silver is converted into a soluble sulphate, which is dissolved out by lixiviating the roasted ore with hot water, the silver being readily precipitated from this solution in the metallic state."

It is certain that if an observant, chemically-trained student visited a silver extraction works, and possessed sufficient analytical skill to enable him to secure evidence as to the changes that occur, he would find a set of facts which his training had not enabled him to predict, and he would establish the existence of a set of reactions to the nature of which his chemical reading had hardly given him a clue. The process to be considered is a simple one, but it is typical, and applies to a large proportion of the 7,000,000 ounces of silver annually obtained in the world from cupriferous compounds. He would be confronted with a ton or more of finely-divided material spread in a thin layer over

Digitized by Google

the bed of a reverberatory furnace. Suppose the material is what is known as a complex regulus, as imported into Swansea or produced at Freiberg, to which are added rich native sulphides. The mixture then consists of sulphides mainly of iron and copper, with some sulphide of lead, and contains fifty or sixty ounces of silver to the ton, and a few grains of gold. It may also contain small quantities of arsenic and antimony as arsenides, antimonides, and sulpho-salts, usually with copper as a base.

The temperature of the furnace in which the operation is to be performed is gradually raised, the atmosphere being an oxidizing one. The first effect of the elevation of the temperature is to distil off sulphur, reducing the sulphides to a lower stage of sulphurization. This sulphur burns in the furnace atmosphere to sulphurous anhydride (SO_2), and, coming in contact with the material undergoing oxidation, is converted into sulphuric anhydride (SO_3). It should be noted that the material of the brickwork does not intervene in the reactions, except by its presence as a hot porous mass, but its influence is, nevertheless, considerable. The roasting of these sulphides presents a good case for the study of chemical equilibrium. As soon as the sulphurous anhydride reaches a certain tension, the oxidation of the sulphide is arrested, even though an excess of oxygen be present, and the oxidation is not resumed until the action of the draught changes the conditions of the atmosphere of the furnace, when the lower sulphides remaining are slowly oxidized, the copper sulphide being converted into copper sulphate mainly by the intervention of the sulphuric anhydride formed as indicated. Probably by far the greater part of the iron sulphide only becomes sulphate for a very brief period, being decomposed into the oxides of iron, mainly ferric oxide, the sulphur passing off. Any silver sulphide that is present would have been converted into metallic silver at the outset were it not for the simultaneous presence of other sulphides, notably those of copper and of iron, which enables the silver sulphide to become converted into sulphate. The lead sulphide is also converted into sulphate at this low temperature. The heat is now raised still further with a view to split up the sulphate of copper, the decomposition of which leaves oxide of copper. If, as in this case, the bases are weak, the sulphuric anhydride escapes mainly as such; but when the sulphates of stronger bases are decomposed, the sulphuric anhydride is to a great extent decomposed into a mixture of sulphurous anhydride and oxygen. The sulphuric anhydride, resulting from the decomposition of this copper sulphate, converts the silver into sulphate, and maintains it as such, just as, in turn, at a lower temperature, the copper itself had been maintained in the form of sulphate by the sulphuric anhydride eliminated from the iron sulphide. When only a little of the copper sulphate remains undecomposed, the silver sulphate begins to split up, and the furnace charge must therefore be immediately withdrawn, or the whole of the silver sulphate would be converted into metallic silver, partly by the direct action of heat alone and partly by reactions such as those shown in the following equations:—

$$Ag_2SO_4 + 4Fe_3O_4 = 2Ag + 6Fe_2O_3 + SO_2,$$
$$Ag_2SO_4 + Cu_2O = 2Ag + CuSO_4 + CuO.$$

If the charge were not withdrawn, the silver would thus be effectually removed from the solvent action of water, and the smelter's efforts would have failed entirely. The charge still contains lead sulphate, which cannot be completely decomposed at any temperature attainable in the roasting furnace, except in the presence of silica, and it is well to leave it where it is if the residue has subsequently to be smelted with a view to the extraction of the gold. The elimination of arsenic and antimony gives rise to problems of much interest, and again confronts the smelter with a case of chemical equilibrium. For the sake of brevity it will be well for the present to limit the consideration to the removal of antimony, which may be supposed to be present as sulphide. Some sulphide of antimony is distilled off, but this is not its only mode of escape. An attempt to remove antimony by rapid oxidation would be attended with the danger of converting it into insoluble antimoniates of the metals present in the charge. In the early stages of the roasting it is therefore necessary to employ a very low temperature, and the presence of steam is found to be useful as a source of hydrogen, which removes sulphur as hydrogen sulphide, the gas being freely evolved. The reaction

$$Sb_2S_3 + 3H_2 = 3H_2S + 2Sb$$

between hydrogen and sulphide of antimony is, however, endothermic, and could not, therefore, take place without the aid which is afforded by external heat. The facts appear to be as follows: sulphide of antimony, when heated, dissociates, and the tension of the sulphur vapour would produce a state of equilibrium if the sulphur thus liberated were not seized by the hydrogen and removed from the system. The equilibrium is thus destroyed, and fresh sulphide is dissociated; the general result being that the equilibrium of the system is continually restored and destroyed until the sulphide is decomposed. The antimony combines with oxygen, and escapes as volatile oxide, as does also the arsenic, a portion of which is volatilized as sulphide.

The main object of the process which has been considered is the formation of soluble sulphate of silver. If arsenic and antimony have not been eliminated, their presence at the end of the operation would be specially inconvenient, as they give rise to the formation of arseniate and antimoniate of silver, insoluble in water, which may necessitate the treatment of the residues by an entirely different process from that which has hitherto been considered.

It will have been evident that effecting this series of changes demands the exercise of the utmost skill, care, and patience. The operations beginning at a dull red heat, or a temperature of some 500°, are completed at 700°, within a range, that is, of 200°. Judicious stirring has been necessary to prevent the formation of crusts of sulphates, which would impede the reactions, and, as has been shown, an undue elevation of temperature within a very limited range would, at any stage, have been fatal to the success of the operation. It is difficult to appreciate too highly the delicacy of sight and touch which enables an operator to judge by the aid of rough tests, but mainly from the tint of the streak revealed when the mass is rabbled, whether any particular stage has or has not been reached, and it will be obvious that the requisite skill is acquired solely by observation and experiment. The technical instructor may impart information as to the routine to be followed, and the appearances to be observed, but scientific knowledge of a high order can alone enable the operator to contend with the disturbing influences introduced by the presence of unexpected elements or by untoward variations in temperature. In the training of a metallurgist it is impossible to separate education from instruction, and the above description of a very ordinary operation will show the intimate relations between science and practice which are characteristic of metallurgical operations. Practice is dependent on science for its advancemement, but scientific workers too often hesitate to attack metallurgical problems, and to devote the resources of modern investigation to their solution, because they are not aware of the great interest of the physical and chemical problems which are connected with many very simple metallurgical processes, especially with those that are conducted at high temperatures.

Proceeding yet one step further, suppose that the copper-smelter takes possession of the residual mass, consisting mainly of oxide of copper, he would smelt it with fresh sulphide ores, and obtain, as a slag from the earthy matters of the ore, a ferrous silicate containing some small proportion of copper. The displacement of the copper from this silicate may be effected by fusing it with sulphide of iron, a fusible sulphide of iron and copper being formed, which readily separates from the slag. By this reaction some twenty thousand tons of copper are added to the world's annual production. Proceeding yet a step further, suppose the smelter to have reduced his copper to the metallic state. If arsenic had been originally present in the ore, and had not been eliminated entirely in the roasting, extraordinary difficulties will be met with in the later stages of the process, in extracting small quantities of arsenic which resist the smelter's efforts. Copper, moreover, containing arsenic cannot be "overpoled," as the presence of arsenic hinders the reducing action of gases on the copper. The amount of arsenic which the copper-smelter has to remove may vary from mere traces up to 1 per cent., and if the copper is destined for the use of the electrical engineer, he will insist on its being as pure as possible, for the presence of a trace of arsenic would materially increase the electrical resistance of the copper, and would be fatal to its use in submarine telegraphy. If, on the other hand, the copper is intended for the maker of locomotive fire-boxes, he will encourage the retention of small quantities of arsenic, as it is found to actually increase the endurance of the copper, and the smelter will in such a case have no inducement to employ the basic furnace lining which Mr. Gilchrist has offered him, nor will he care to use the special methods for the removal of arsenic

Digitized by Google

with which he is familiar. It may all seem simple enough, but the modern process of copper-smelting has been laboriously built up, and has a long and interesting pedigree which may be traced to at least the eighth century, when Geber described the regulus, "coarse metal," as being "black mixed with livid," and our familiar "blue metal" as being "of a most clean and pleasant violet colour," and indicated the reason for the difference.[1]

(3) The foregoing instances have been given to indicate the general nature of metallurgical chemistry. It will be well now to show how the great advances in metallurgical practice have been made in the past, with a view to ascertain what principles should guide us in the future.

It is a grave mistake to suppose that in industry, any more than in art, national advance takes place always under the guidance of a master possessed of some new gift of invention; yet we have been reminded that we are apt to be reverent to these alone, as if the nation had been unprogressive and suddenly awakened by the genius of one man. The way for any great technical advance is prepared by the patient acquisition of facts by investigators of pure science. Whether the investigators are few or many, and consequently whether progress is slow or rapid, will depend in no small measure on the spirit of the nation as a whole. A genius whose practical order of mind enables him to make some great invention suddenly arises, apparently by chance, but his coming will, in most cases, be found to have "followed hard upon" the discovery by some scientific worker of an important fact, or even the accurate determination of a set of physical constants. No elaborate monograph need have reached the practical man—a newspaper paragraph, or a lecture at a Mechanics' Institute may have been sufficient to give him the necessary impulse; but the possessors of minds which are essentially practical often forget how valuable to them have been the fragments of knowledge they have so insensibly acquired that they are almost unconscious of having received any external aid.

The investigating and the industrial faculty are sometimes, though rarely, united in one individual. Rapid advance is often made by those who are untrammelled by a burden of precedent, but it should be remembered that though the few successes, which have been attained in the course of ignorant practice, may come into prominence, none of the countless failures are seen.

I would briefly direct attention to certain processes which have been adopted since the year 1849, when Dr. Percy presided over this Section at Birmingham, a great metallurgical centre. In that year the President of the Association made a reference to metallurgy, a very brief one, for Dr. Robinson only said "the manufacture of iron has been augmented six-fold by the use of the puddling-furnace and the hot-blast, both gifts of theory"; and so, it may be added, are most of the important processes which have since been devised. Take the greatest metallurgical advance of all, the Bessemer process, which has probably done more than any other to promote the material advance of all countries. It was first communicated to the world at the Cheltenham Meeting of the British Association, 1856. Its nature is well known, and I need only say that it depends on the fact that when air is blown through a bath of impure molten iron, sufficient heat is evolved by the rapid combustion of silicon, manganese, and carbon, to maintain the bath fluid after these elements have been eliminated, there being no external source of heat, as there is in the puddling furnace or the refinery hearth. We have recently been told that, at an early and perilous stage of the Bessemer process, confidence in the experiments was restored by the observation that the temperature of the "blown" metal contained in a crucible was higher than that of the furnace in which it was placed. The historian of the future will not fail to record that the way for the Bessemer process had been prepared by the theoretical work of Andrews, 1848, and of Favre and Silbermann, 1852, whose work on the calorific power of various elements showed that silicon and phosphorus might be utilized as fuel, because great heat is engendered by their combustion.

The basic process for removing phosphorus, a process of great national importance, the development of which we owe to Thomas and Gilchrist, is entirely the outcome of purely theoretical teaching, in connection with which the names of Grüner and Percy deserve special mention. In the other great group of processes for the production of steel, those in which Siemens's regenerative furnace is employed, we have the direct influence of a highly trained theorist, who concluded his address as President of this Association in 1882 by reminding us that "in the great workshop of Nature there is no line of demarcation to be drawn between the most exalted speculation and commonplace practice." The recent introduction of the method of heating by radiation is, of course, the result of purely theoretical considerations.

The progress in the methods of extracting the precious metals has been very great, both on the chemical and engineering sides, but it is curious that in the metallurgy of gold and silver, many ancient processes survived which were arrived at empirically—a noteworthy exception being presented by the chlorine process for refining gold, by the aid of which many millions sterling of gold have been purified. The late Mr. H. B. Miller based this process for separating silver from gold on the knowledge of the fact that chloride of gold cannot exist at a bright red heat. The tension of dissociation of chloride of gold is high, but the precious metal is not carried forward by the gaseous stream, at least not while chloride of silver is being formed.

The influence of scientific investigation is, however, more evident in that portion of the metallurgic art which deals with the adaptation of metals for use, rather than with their actual extraction from the ores.

Only sixteen years ago Sir Nathaniel Barnaby, then Director of Naval Construction, wrote, "Our distrust of steel is so great that the material may be said to be altogether unused by private ship-builders, . and marine engineers appear to be equally afraid of it." He adds, "The question we have to put to the steel makers is, What are our prospects of obtaining a material which we can use without such delicate manipulation and so much fear and trembling?" All this is changed, for, as Mr. Elgar informs me, in the year ending on June 30 last, no less than 401 ships, of three-quarters of a million gross tonnage, were being built of steel in the United Kingdom.

Why is it, then, that steel has become the material on which we rely for our ships and for our national defence, and of which such a splendid structure as the Forth Bridge is constructed? It is because, side by side with great improvement in the quality of certain varieties of steel, which is the result of using the open-hearth process, elaborate researches have shown what is the most suitable mechanical and thermal treatment for the metal; but the adaptation of steel for industrial use is only typical, as the interest in this branch of metallurgy generally appears for the moment to be centred in the question whether metals can, like many metalloids, pass under the application of heat or mechanical stress from a normal state to an allotropic one, or whether metals may even exist in numerous isomeric states.

It is impossible to deal historically with the subject now, further than by stating that the belief of more than one "modification" is old and widespread, and was expressed by Paracelsus, who thought that copper "contains in itself its female," which could be isolated so as to give "two metals" . . . "different in their fusion and malleability" as steel and iron differ. Within the last few years Schützenberger has shown that two modifications of copper can exist, the normal one having a density of 8·95, while that of the allotropic modification is only 8·0, and is moreover rapidly attacked by dilute nitric acid, which is without action on ordinary copper. It may be added that Lord Rayleigh's plea for the investigation of the simpler chemical reactions has been partly met, in the case of copper, by the experiments conducted by V. H. Veley on the conditions of chemical change between nitric acid and certain metals.

Bergmann, 1781, actually calls iron polymorphous, and says that it plays the part of many metals, "Adeo ut jure dici queat polymorphum ferrum plurium simul metallorum vices sustinere." Osmond has recently demonstrated the fact that at least two modifications of iron must exist.

Prof. Spring, of Liége, has given evidence that in cooling

[1] It must not be supposed that when commercially pure copper lies on the furnace bed, ready to be transferred to moulds, that its turbulent career of reactions is over. It might be thought that the few tenths per cent. of impurity, dissolved oxide, and occluded gas, are so far attenuated by distribution that their interactions must be insignificant. This is far from being the case. I believe the bath of metal is seething from its reactions until the copper is solid, and then polymerization proceeds. There may not be a sharply-defined, critical range of temperature within which the metal can alone be successfully worked, and which varies, as regards its starting-point, with the kind of impurity present, as is the case with steel; but evidence of molecular change in the solid metal is afforded by the pyrometric curves of cooling referred to on p. 405, and by the singular behaviour as regards electrical resistance, of various samples of copper, in which chemical analysis hardly reveals a difference.

Digitized by Google

lead-tin alloys polymerization may take place after the alloys have become solid, and it seems to be admitted that the same cause underlies both polymerization and allotropy. The phenomenon of allotropy is dependent upon the number of the atoms in each molecule, but we are at present far from being able to say what degree of importance is to be attached to the relative distance between the atoms of a metal or to the "position of one and the same atom" in a metallic molecule, whether the metal be alloyed or free, and it must be admitted that in this respect organic chemistry is far in advance of metallurgic chemistry. I cannot, as yet, state what is the atomic grouping in the brilliantly-coloured gold-aluminium alloy, $AuAl_2$, which I have had the good fortune to discover, but, in it, the gold is probably present in the same state as that in which it occurs in the purple of cassius.

Much valuable information on the important question of allotropy in metals has already been gathered by Pionchon, Ditte, Moissan, Le Chatelier, and Osmond, but reference can only be made to the work of the two latter. Le Chatelier concludes that in metals which do not undergo molecular transformation the electrical resistance increases proportionally to the temperature. The same law holds good for other metals at temperatures above that at which their last change takes place; for example, in the case of nickel above 340°, and in that of iron above 850°.

It is probable that minute quantities of foreign matter, which profoundly modify the structure of masses of metal, also induce allotropic changes. In the case of the remarkable action of impurities upon pure gold I have suggested that the modifications which are produced may have direct connection with the periodic law of Mendeleeff, and that the causes of the specific variations in the properties of iron and steel may thus be explained. The question is of great industrial importance, especially in the case of iron; and Osmond, whose excellent work I have already brought before the members of this Association in a lecture delivered at Newcastle in 1889, has especially studied the influence upon iron exerted by certain elements. He shows that elements whose atomic volumes are smaller than that of iron delay, during the cooling of a mass of iron from a red heat, the change of the β, or hard variety of iron, to the α, or soft variety. On the other hand, elements whose atomic volumes are greater than that of iron tend to hasten the change of β to α iron. It is, however, unnecessary to dwell upon this subject, as it was dealt with last year in the address of the President of the Association.

It may be added that the recent use of nickel-steel for armour-plate, and the advocacy of the use of copper-steel for certain purposes, is the industrial justification of my own views as to the influence of the atomic volume of an added element on the mechanical properties of iron, and it is remarkable that the two bodies, silicon and aluminium, the properties of which when in a free state are so totally different, should, nevertheless, when they are alloyed with iron, affect it in the same way. Silicon and aluminium have almost the same atomic volumes.

The consequences of allotropic changes which result in alteration of structure are very great. The case of the tin regimental buttons which fell into a shapeless heap when exposed to the rigorous winter at St. Petersburg, is well known. The recent remarkable discovery by Hopkinson of the changes in the density of nickel-steel (containing 22 per cent. of nickel) which are produced by cooling to − 30°, affords another instance. This variety of steel, after being frozen, is readily magnetizable, although it was not so before; its density, moreover, is permanently reduced by no less than 2 per cent. by the exposure to cold; and it is startling to contemplate the effect which would be produced by a visit to the Arctic regions of a ship of war built in a temperate climate of ordinary steel, and clad with some three thousand tons of such nickel-steel armour; the shearing which would result from the expansion of the armour by exposure to cold would destroy the ship. Experimental compound armour-plates have been made, faced with 25 per cent. nickel-steel, but it remains to be seen whether a similar though lessened effect would be produced on the steel containing 5 to 7 per cent. of nickel, specially studied by J. Riley, the use of which is warmly advocated for defensive purposes. Further information as to the molecular condition of nickel-steel has within the last few weeks been given by Mercadier, who has shown that alloying iron with 25 per cent. of nickel renders the metal isotropic.

The molecular behaviour of alloys is indeed most interesting. W. Spring has shown, in a long series of investigations, that alloys may be formed at the ordinary temperature, provided that minute particles of the constituent metals are submitted to great pressure. W. Hallock has recently given strong evidence in favour of the view that an alloy can be produced from its constituent metals with but slight pressure if the temperature to which the mass is submitted be above the melting-point of the alloy, even though it be far below the melting-point of the most easily fusible constituent. A further instance is thus afforded of the fact that a variation of either temperature or pressure will effect the union of solids. It may be added that B. C. Damien is attempting to determine what variation in the melting-point of alloys is produced by fusing them under a pressure of two hundred atmospheres. Italian physicists are also working on the compressibility of metals, and F. Boggio-Lera has recently established the existence of an interesting relation between the coefficient of cubic compressibility, the specific gravity, and the atomic weight of metals.

Few questions are more important than the measurement of very high temperatures. Within the last few years H. Le Chatelier has given us a thermo-couple of platinum with platinum containing 10 per cent. of rhodium, by the aid of which the problem of the measurement of high temperatures has been greatly simplified. A trustworthy pyrometer is now at hand for daily use in works, and the liberality of the Institution of Mechanical Engineers has enabled me to conduct an investigation which has resulted in the adoption of a simple appliance for obtaining, in the form of curves, photographic records of the cooling of masses of metal. A report on the subject has already been submitted to a Committee, of which the Director-General of Ordnance Factories is the Chairman; and Dr. Anderson, to whom I am indebted for valuable assistance and advice, intends to add this new method for obtaining autographic curves of pyrometric measurements to the numerous self-recording appliances used in the Government factories which he controls. It has proved to be easy to ascertain, by the aid of this pyrometer, what thermal changes take place during the cooling of molten masses of alloys, and it is possible to compare the rate of cooling of a white-hot steel ingot at definite positions situated respectively near its surface and at its centre, and thus to solve a problem which has hitherto been considered to be beyond the range of ordinary experimental methods. Some of the curves already obtained are of much interest, and will be submitted to the Section. It is probable that the form of the curve which represents the solidification and cooling of a mass of molten metal affords an exceedingly delicate indication as to its purity.

Prof. H. E. Armstrong holds that the molecules of a metal can unite to form complexes with powers of coherence which vary with the presence of impurity. Crookes, by a recent beautiful investigation, has taught us how electrical evaporation of solid metals may be set up *in vacuo*, and has shown that even an alloy may be decomposed by such means. We may hope that such work will enable us to understand the principles on which the strength of materials depends.

Before leaving the consideration of questions connected with the molecular constitution of metals, I would specially refer to the excellent work of Heycock and Neville, who have extended to certain metals with low melting-point Raoult's investigations on the effect of impurity on the lowering of the freezing-point of solids. With the aid of one of my own students, H. C. Jenkins, I have further extended the experiments by studying the effect of impurity on the freezing-point of gold. Ramsay, by adopting Raoult's vapour-pressure method, has been led to the conclusion that when in solution in mercury the atom of a metal is, as a rule, identical with its molecule. The important research on the liquation of alloys has been extended by E. Matthey to the platinum-gold and palladium-gold series, in which the manipulation presented many difficulties; and E. J. Ball has studied the cases presented by the antimony copper-lead series. Dr. Alder Wright has continued his own important investigation upon ternary alloys; and A. P. Laurie has worked on the electromotive force of the copper-zinc and copper-tin and gold-tin series, a field of research which promises fruitful results.

In no direction is advance more marked than in the mechanical testing of metals, in which branch of investigation this country, guided by Kirkaldy, undoubtedly took the leading part, and in connection with which Kennedy and Unwin have established world-wide reputations. I would also specially mention the work which has been carried on at the Government testing works at Berlin under Dr. Wedding, and the elaborate

Digitized by Google

investigations conducted at the Watertown Arsenal, Massachusetts, not to mention the numerous Continental testing laboratories directed by such men as Bauschinger, Jenny, and Tetmajer. Perhaps the most important recent work is that described by Prof. Martens, of Berlin, on the influence of heat on the strength of iron.

I might have dwelt at length on all these matters without doing half the service to metallurgy that I hope to render by earnestly pleading for the more extended teaching of the subject throughout the country, and for better laboratories, arranged on the model of engineering laboratories, in which the teaching is conducted with the aid of complete, though small, "plant." The Science and Art Department has done great and lasting service by directing that metallurgy shall be taught practically, but much remains to be done. With regard to laboratories in works, which are too often mere sheds, placed, say, behind the boiler-house, when may we hope to rival the German chemical firm which has recently spent £19,000 upon its laboratories, in which research will be vigorously conducted? There is hardly any branch of inorganic chemistry which the metallurgist can afford to neglect, while many branches both of physics and mechanics are of the utmost importance to him.

The wide range of study upon which a metallurgical student is rightly expected to enter is leading, it is to be feared, to diminution in the time devoted to analytical chemistry, and this most serious question should be pressed upon the attention of all who are responsible for the training of our future chemists. There can be no question that sufficient importance is not attached to the estimation of "traces," an analysis being considered to be satisfactory if the constituents found add up to 99·9, although a knowledge as to what elements represent the missing 0·1 may be more useful in affording an explanation of the defects in a material than all the rest of the analysis. This matter is of growing interest to practical men, and may explain their marked preference for chemists who have been trained in works, to those who have been educated in a college laboratory.

The necessity for affording public instruction in mining and metallurgy, with a view to the full development of the mineral wealth of a nation, is well known. The issues at stake are so vast, that in this country it was considered desirable to provide a centre of instruction in which the teaching of mining and metallurgy should not be left to private enterprise or even intrusted to a corporation, but should be under the direct control of the Government. With this end in view, the Royal School of Mines was founded in 1851, and has supplied a body of well-trained men who have done excellent service for the country and her colonies. The Government has recently taken a step in advance, and has further recognized the national importance of the teaching of mining and metallurgy by directing that the School of Mines shall be incorporated with the Royal College of Science, which is, I believe, destined to lead the scientific education of the nation.

It is to be feared that as regards metalliferous mining our country has seen its best days, but the extraordinary mineral wealth of our colonies has recently been admirably described by my colleague, Prof. Le Neve Foster, in the inaugural lecture he delivered early in the present year on his appointment to the chair so long held by Sir Warington Smyth (*Engineering*, vol. li., p. 200 *et seq.*). We shall, however, be able to rightly estimate the value of our birthright when the Imperial Institute is opened next year, and the nation will have reason to be grateful to Sir Frederick Abel for the care he is devoting to the development of this great institution, which will become the visible exponent of the splendours of our Indian and colonial resources, as well as a centre of information.

The rapid growth of technical literature renders it unnecessary for a President of a Section to devote his address to recording the progress of the subject he represents. As regards the most important part of our national metallurgy, this has, moreover, been admirably done by successive Presidents of the Iron and Steel Institute, but it may have been expected that references would have been made to the main processes which have been adopted since Percy occupied this chair in 1849. I have not done so, because an enumeration of the processes would have been wholly inadequate, and a description of them impossible in the time at my disposal. Nevertheless, it may be well to remind the Section of a few of the more prominent additions the art has received in the last half-century, and to offer a few statements to show the magnitude on which operations are conducted. As regards iron, in the last twenty-five years the price of steel has been reduced from £55 per ton to £5 per ton; but, after giving the world the inestimable boon of cheap steel by the labours of Bessemer and of Siemens, we were somewhat slow to accept the teaching of experiment as to the best method of treating the new material; on the other hand, Hadfield has brought manganese steel and aluminium steel within the reach of the manufacturer, and J. Riley has done much to develop the use of nickel-steel.

In the case of copper, we have mainly contributed to the extraordinary development of wet processes for its extraction from poor sulphides, and have met the great demands for pure metal by the wide adoption of electrolytic processes.

As regards the precious metals, this country is well to the front, for Great Britain and her colonies produce about 38 per cent. of the gold supply of the world; and it may be well to add, as an indication of the scale on which operations are conducted, that in London alone one ton of gold and five tons of silver bullion can easily be refined in a day. No pains have been spared in perfecting the method of assay by which the value of gold and silver is ascertained, and during my twenty years' connection with the Royal Mint I have been responsible for the accuracy of the standard fineness of no less than five hundred and fifty-five tons of gold coin, of an aggregate value of seventy millions five hundred thousand pounds sterling. In the case of the platinum industry we owe its extraordinary development to the skill and enterprise of successive members of the firm of Johnson, Matthey, and Co., who in later years have based their operations upon the results of the investigations of Deville and Debray. Some indication of the value of the material dealt with may be gathered from the statement that two and a half hundredweight of platinum may easily be melted in a single charge, and that the firm, in one operation, extracted a mass of palladium valued at £30,000 from gold-platinum ore actually worth more than a million sterling.

I wish it were possible to record the services of those who have advanced metallurgy in connection with this Association, but the limitations of time render it difficult to do more than to refer to some honoured names of past presidents of this Section. Michael Faraday, President of this Section in 1837 and 1846, prepared the first specimen of nickel-steel, an alloy which seems to have so promising a future, but we may hardly claim him as a metallurgist; nor should I be justified in referring, in connection with metallurgical research, to my own master, Graham, President of this Section in 1839, and again in 1844, were it not that his experiments on the occlusion of gases by metals have proved to be of such extraordinary practical importance in connection with the metallurgy of iron. Sir Lyon Playfair presided over this Section in 1855, and again in 1859. His work in connection with Bunsen on the composition of blast-furnace gases was published in the Report of this Association in 1847, and formed the earliest of a group of researches, amongst which those of Sir Lowthian Bell proved to be of so much importance. The latter was President of this Section in 1889. Sir F. Abel, President of this Section in 1877, rendered enduring service to the Government by his elaborate metallurgical investigations in connection with materials used for guns and projectiles, as well as for defensive purposes. I will conclude this section of the address by a tribute to the memory of Percy. He may be said to have created the English literature of metallurgy, to have enriched it with the records of his own observations, and to have revived the love of our countrymen for metallurgical investigation. His valuable collection of specimens, made while Professor at the Royal School of Mines, is now appropriately lodged at South Kensington, and will form a lasting memorial of his labours as a teacher. He exerted very noteworthy influence in guiding the public to a just appreciation of the labours of scientific men, and he lived to see an entire change in the tone of the public press in this respect. In the year of Percy's presidency over this Section the *Times* gave only one-tenth of a column to a summary of the results of the last day but one of the meeting, although the usual discourse delivered on the previous evening had been devoted to a question of great importance—"The Application of Iron to Railway Purposes." Space was, however, found for the interesting statement that the "number of Quakeresses who attended the meetings of the Sections was not a little remarkable." Compare the slender record of the *Times* of 1849 with its careful chronicle of the proceedings at any recent meeting of the Association.

In drawing this address to a close, I would point to the great importance of extending the use of the less known metals. Attention is at present concentrated on the production of aluminium, and reference has already been made to the Cowles process, in which, as in that of Héroult, the reduction of alumina is effected by carbon, at the very high temperature of the electric arc; while, on the other hand, in the Kleiner and similar processes, the electric current acts less as a source of heat than by decomposing a fluid bath, the aluminium being isolated by electrolytic action; and doubtless in the immediate future, there will be a rapid increase in the number of metallurgical processes that depend on reactions which are set up by submitting chemical systems to electric stress. Incidental reference should be made to the growing importance of sodium, not only in cheapening the production of aluminium, but as a powerful weapon of research. In 1849, when Percy was President of this Section, magnesium was a curiosity; now its production constitutes a considerable industry. We may confidently expect to see barium and calcium produced on a large scale as soon as their utility has been demonstrated by research. Minerals containing molybdenum are not rare; and the metal could probably be produced as cheaply as tin if a use were to be found for it. The quantities of vanadium and thallium which are available are also far from inconsiderable; but we as yet know little of the action of any of these metals when alloyed with others which are in daily use. The field for investigation is vast indeed, for it must be remembered that valuable qualities may be conferred on a mass of metal by a very small quantity of another element. The useful qualities imparted to platinum by iridium are well known. A small quantity of tellurium obliterates the crystalline structure of bismuth; but we have lost an ancient art, which enabled brittle antimony to be cast into useful vessels. Two-tenths per cent. of zirconium increases the strength of gold enormously, while the same amount of bismuth reduces the tenacity to a very low point. Chromium, cobalt, tungsten, titanium, cadmium, zirconium, and lithium are already well known in the arts, and the valuable properties which metallic chromium and tungsten confer upon steel are beginning to be generally recognized, as the last Exhibition at Paris abundantly showed; but as isolated metals we know but little of them. Is the development of the rarer metals to be left to other countries? Means for the prosecution of research are forthcoming, and a rich reward awaits the labours of chemists who could bring themselves to divert their attention, for even a brief period, from the investigation of organic compounds, in order to raise alloys from the obscurity in which they are at present left.

It must not be forgotten that metallurgical enterprise rests on (1) scientific knowledge, (2) capital, and (3) labour; and that, if the results of industrial operations are to prove remunerative, much must depend on the relation of these three elements, though it is difficult to determine accurately their relative importance. A modern ironworks may have an army of ten thousand workmen, and commercial success or failure will depend in no small measure on the method adopted in organizing the labour. The relations between capital and labour are of so much interest at the present time that I do not hesitate to offer a few words on the subject.

Many examples might be borrowed from metallurgical enterprises in this and other countries to show that their nature is often precarious, and that failure is easily induced by what appear to be comparatively slight causes. Capitalists might consequently tend to select Government securities for investment in preference to metallurgical works, and the labouring population would then severely suffer. It is only reasonable, therefore, that if capitalists are exposed to great risks, they should, in the event of success, receive the greater part of the profits. There is a widespread feeling that the interests of capital and labour must be antagonistic, and as it is impossible to ignore the fact that the conflict between them is giving rise to grave apprehension, it becomes the duty of all who possess influence to strive not merely for peace, but to range themselves on the side of justice and humanity. The great labour question cannot be solved except by assuming as a principle that private ownership must be held inviolable; but it must be admitted that there was a time when capital had become arbitrary, and some kind of united action on the part of workmen was needed in self-defence. If, however, we turn to the action of the leaders of trades unions in the recent lamentable strikes, we are presented with a picture which many of us can only view as that of tyranny of the most close and oppressive kind, in which individual freedom cannot even be recognized. There are hundreds of owners of works who long to devote themselves to the true welfare of those they employ, but who can do little against the influence of the professional agitator, and are merely saddened by contact with prejudice and ignorance. I believe the view to be correct that some system by which the workman participates in the profits of enterprise will afford the most hope of putting an end to labour disputes, and we are told that profit-sharing tends to destroy the workmen's sense of social exclusion from the capitalistic board, and contents him by elevating him from the precarious position of a hired labourer. No pains should, therefore, be spared in perfecting a system of profit-sharing.

Pensions for long service are great aids to patience and fidelity, and very much may be hoped from the fact that strenuous efforts are being made by men really competent to lead. The Report of the Labour Commission which is now sitting will be looked for with keen interest. Watchful care over the health, interests, and instruction of the employed is exercised by many owners of works; and in this respect the Dowlais Works, which are being transplanted into your midst at Cardiff, have long presented a noteworthy example. Workmen must not forget that the choice of their own leaders is in their own hands, and on this the future mainly depends. "We may lay it down as a perpetual law that workmen's associations should be so organized and governed as to furnish the best and most suitable means for attaining what is aimed at—that is to say, for helping each individual member to better his condition to the utmost in body, mind, and property." These words will be found in the Encyclical Letter which Pope Leo XIII. has recently issued on the "Condition of Labour." To me it is specially interesting that the Bishop of Rome in his forcible appeal again and again cites the opinion of St. Thomas Aquinas, who was a learned chemist as well as a theologian.

Those of us who realize that "the higher mysteries of being, if penetrable at all by human intellect, require other weapons than those of calculation and experiment," should be fully sensible of our individual responsibility. Seeing that the study of the relations between capital and labour involves the consideration of the complex problems of existence, the solution of which is at present hidden from us, we shall feel with Andrew Lang that "where, as matter of science, we know nothing, we can only utter the message of our temperament." My own leads me to hope that the patriotism of the workmen will prevent them from driving our national industries from these shores; and I would ask those to whom the direction of the metallurgical works of this country is confided to remember that we have to deal both with metals and with men, and have reason to be grateful to all who extend the boundaries, not only of our knowledge, but also of our sympathy.

SECTION D.

BIOLOGY.

OPENING ADDRESS BY FRANCIS DARWIN, M.A., M.B., F.R.S., FELLOW OF CHRIST'S COLLEGE, CAMBRIDGE, PRESIDENT OF THE SECTION.

On Growth-curvatures in Plants.

A SEEDLING plant, such as a young sunflower, when growing in a state of nature, grows straight up towards the open sky, while its main root grows straight down towards the centre of the earth. When it is artificially displaced, for instance by laying the flower-pot on its side, both root and stem execute certain curvatures by which they reach the vertical once more. Curvatures such as these, whether executed in relation to light, gravitation, or other influences, may be grouped together as growth-curvatures, and it is with the history of our knowledge on this subject that I shall be occupied to-day. I shall principally deal with geotropic curvatures, or those executed in relation to gravitation, but the phenomena in question form a natural group, and it will be necessary to refer to heliotropism, and, indeed, to other growth-curvatures. The history of the subject divides into two branches, which it will be convenient to study separately.

When a displaced apogeotropic organ curves so as to become once more vertical, two distinct questions arise, which may be briefly expressed thus:—

Digitized by Google

(1) How does the plant recognize the vertical line; how does it know where the centre of the earth is?

(2) In what way are the curvatures which bring it into the vertical line executed?

The first is a question of irritability, the second of the mechanism of movement. Sachs has well pointed out that these two very different questions have been confused together (*Arbeiten*, ii. p. 282, 1879). They should be kept as distinct as the kindred questions, How, by what nervous apparatus, does an animal perceive changes in the external world; and how, by what muscular machinery, does it move in relation to such changes?

The history of our modern knowledge of geotropism may conveniently begin with Hofmeister's researches, because in an account of his work some of the points which re-occur in recent controversy are touched, and also because in studying his work the necessity of dividing the subject into the two above-named headings, Irritability and Mechanism, will be more clearly perceived.

In 1859 (*Berichte d. k. Sächs. Ges. d. Wiss.*), Hofmeister published his researches on the effect of disturbance, such as shaking or striking a turgescent shoot. This appears at first sight sufficiently remote from the study of geotropism, but the facts published in this work were the basis of the theory of geotropism formed by Hofmeister and accepted with some modification by Sachs. When an upright, vigorously-growing, turgescent shoot is struck at its base the upper end is made to curve violently towards the side from which the blow came. When the shoot comes to rest it is found to be no longer straight, but to have acquired a permanent bend towards the side on which it was struck. In explaining this phenomenon Hofmeister described those conditions of growth which give rise to what is known as the tension of tissues; these facts are still an important part of botanical study, though they hold quite a different position from that assigned to them by Hofmeister. The classification into active or erectile tissue and passively extended tissue was then first made. The pith, which is compressed, and strives to become longer, is the active or erectile part, the cortical and vascular constituents being passively extended by the active tissue. Hofmeister showed that when the shoot is violently bent the elasticity of the passive tissues on the convex side is injured by overstretching. The system must assume a new position of equilibrium; the passive tissues are now no longer equally resisting on the two sides, and the shoot must necessarily assume a curvature towards that side on which passive tissues are most resisting.

In a second paper, in 1860, Hofmeister (*Berichte d. k. Sächs. Ges. d. Wiss.*) applied these principles to the explanation of geotropism. It is true that in his second paper he does not refer to the former one, but I think that it can hardly be doubted that the knowledge which supplied the material for his paper of 1859 suggested the theory set forth in 1860. He had shown that in the system of tensions existing in a turgescent shoot lay the power of producing artificial curvatures, and he applied the same principle to the natural curvatures. When an apogeotropic organ is placed in a horizontal position, Hofmeister [1] supposed that the resisting tissues on the lower side became less resisting, so that they yielded more readily than those on the upper side to the longitudinal pressure of the turgescent pith. The system in such a case comes to rest in a new position, the shoot curving upwards; the passive tissues on the upper and lower sides once more resist the expansion of the pith in equal degrees. In this way Hofmeister hit on an explanation which, as far as mechanism is concerned, is in rough outline practically the same as certain modern theories, which will be discussed in the sequel.

His views resembled more modern theories in this, too: he clearly recognized that they were, *mutatis mutandis*, applicable to acellular [2] organs. The manner in which Hofmeister compared the mechanics of multicellular and acellular parts was curious; nowadays we compare the turgescent pith of a growing shoot with the hydrostatic pressure inside the acellular organ. Just as the pressure inside a single cell stretches the cell-walls, so in a growing shoot the turgescent pith stretches the cortex. As pith is to cortex, so is cell-pressure to cell-membrane. But Hofmeister would not have accepted any such comparison. In the case of acellular organs he localized both the erectile and passive tissues in the membrane. The cuticle was said to be passively extended by the active growth of the inner layers of the cell-wall.

It is remarkable that the obvious source of power which the pressure of the cell-sap against the cell-walls supplies should have been so much neglected. This may perhaps be accounted for as a revulsion against the excessive prominence given to osmosis in the works of Dutrochet.

The great fault of Hofmeister's views was the purely mechanical manner in which he believed changes in extensibility in the passive tissues to be brought about. When an apogeotropic shoot is placed horizontal there would be a tendency, according to Hofmeister, for the resisting passive tissues along the lower side of the shoot to become waterlogged owing to the fluid in the shoot gravitating towards that side. They would thus be rendered more extensible, and the shoot would bend up, since its lower parts would yield to the erectile tissues in the centre. Such a conception excludes the idea of gravitation acting as a stimulus, and tends to keep geotropism out of the category in which it now takes its place along with such obvious cases of response to stimulation as the movements of Mimosa. In this respect it was a retrogression from the views of some earlier writers. Dutrochet's clear statement (1824) as to growth-curvatures being an affair of stimulus and response will be quoted lower down. Treviranus, in his "Physiologie" (1838), speaks of geotropism as a *Trieb*, or impulse, and adds that though there is no question of desire or sensation, as in the impulses of animals, yet geotropism must be thought of as something higher than a merely mechanical or chemical action.

In taking such a view Hofmeister naturally neglected the biological side of the study of geotropism. Now, we think of gravitation as a stimulus, which the plant translates according to its needs. The plant, so to speak, knows where the centre of the earth is, and either grows away from it, or towards it, according as either direction suits its mode of existence.

We have seen how Hofmeister's view enabled him to apply a common explanation to acellular and multicellular organisms. But it led him into an error which more than counterbalances the credit due to such a generalization—namely, into separating what are now universally considered parts of a single phenomenon—viz. negative and positive geotropism. He gave totally different explanations of the bending down of a root and the bending up a stem. It is well known that he supposed a root to be plastic, and to bend over by its own weight, like a tallow candle on a hot day or a piece of heated sealing-wax.

The development of a unified view of heliotropism, geotropism, and other similar curvatures is a part of my subject, and for that reason the curious want of unity in Hofmeister's views is interesting.

In 1865, Sachs published his "Experimental-Physiologie." He here accepts Hofmeister's views with certain modifications.

Irritability.

When by a touch on a trigger the explosion of a pistol is caused, we do not say that the pistol is irritable, but when in an organism a similar release of stored-up energy occurs, we apple the term *irritability* to the phenomenon, and we call the influency which produced the change a stimulus. At this time (1865) there was, as far as I can discover, no idea that growth-curvatures were produced by external influences acting as stimuli. Gravitation and light were supposed to act directly, and not as releasing forces. This is all the more remarkable, because Dutrochet [1] had expressed with great clearness the conception which we now hold. He wrote:—"La cause inconnue de l'attraction n'est que la cause occasionelle du mouvement descendant des racines et de l'ascension des tiges; elle n'en est point la cause immédiate; elle agit dans cette circonstance comme agent nervimoteur. Nous verrons plus bas de nouvelles preuves de la généralité de ce fait important en physiologie, savoir que les mouvements visibles des végétaux sont tous des mouvements *spontanés*, exécutés à l'occasion de l'influence d'un agent extérieur et non des mouvements imprimés par cet agent." Nothing could be more to the purpose than this, and it is one of the most curious points in the history of the subject that the

[1] Knight had previously suggested an explanation (Philosophical Transactions, 1806), which is so far similar, that the sinking downwards by gravitation of the juices of the plant is supposed to be the primary cause of apogeotropism. Knight's explanation of positive geotropism is practically the same as Hofmeister's.

[2] Sachs's term *acellular* is, in the present connection, equivalent to *unicellular*.

[1] "Recherches anat. sur la Structure intime, &c." (1824), p. 107. Dutrochet, however, was not consistent in this matter, and later on gave explanations as mechanical as Hofmeister's.

Digitized by Google

botanical mind should have taken more than fifty years to assimilate Dutrochet's view.

In 1868 Albert Bernhard Frank published his valuable "Beiträge zur Pflanzenphysiologie," which was of importance in more than one way. In this work the term "geotropism" was first suggested in imitation of the existing expression "heliotropism." This uniformity of nomenclature had an advantage beyond mere convenience, for it served to emphasize the view that the curvatures were allied in character. His criticisms of Hofmeister and Sachs were directed against the following views:—

(i.) That roots and other positively geotropic organs bend owing to plasticity. By repeating and varying certain older experiments, Frank helped materially to establish the now universally accepted view that positive geotropism is an active, not a passive, curvature, and that it depends, like apogeotropism, on unequal distribution of longitudinal growth. Here, again, he introduced unity, bringing what had been considered different phenomena under a common heading. By studying the distribution of growth and of tension in a variety of curvatures he helped still more to unite them under a common point of view.

(ii.) He showed that Hofmeister's classification of organs into those (1) which have and (2) which have not tension, was valueless in connection with growth-curvatures; that is to say, that apogeotropism is not necessarily connected with the form of longitudinal tension found in growing shoots, and that the distinct kind of tension existing in roots has no connection with their positive geotropism. His work thus served to bring the subject into a more purely physiological condition, not only by his downright opposition to a mechanical theory backed by the great name of Hofmeister, but also by giving importance to physiological individuality.

In 1870, Frank published a more important work, "Die natürliche wagerechte Richtung der Pflanzentheilen." This paper not only tended to unite geotropism and heliotropism by proving the phenomena described to be common to both categories, but it more especially widened the field of view by showing that horizontal growth must be considered as kindred to vertical growth, and thus introduced a new conception of the reaction of plants to light and gravitation which has been most fruitful.

Frank showed that certain parts of plants, for instance the runners of the strawberries, even when kept in the dark, grow horizontally, and when displaced from the horizontal returned to it. Here, said Frank, is a new type of geotropism, neither positive nor negative, but *transverse*. Ten years later Elfving (Sachs's *Arbeiten*, 1880), working in Sachs's laboratory, got similar results with rhizomes of Scirpus, &c. These experiments are more conclusive than Frank's in one way, because the strawberry runners when darkened were in abnormal conditions, whereas the rhizomes used by Elfving were normally freed from light-effects. When a rhizome which has been placed so as to point obliquely upwards, moves down towards the horizontal position it is, according to the old nomenclature, positively geotropic, and, *vice versâ*, when it reaches the horizontal from below it is negatively geotropic. But it cannot be both positively and negatively geotropic. We are bound to assume that it is so organized that it can only assume a position of rest, and continue to grow in a straight line when it is horizontal, just as an ordinary geotropic organ cannot devote itself to rectilinear growth unless it is vertical. In this way Frank's conception of transverse geotropism paved the way for the theory that there are a variety of different organizations (or, as we may now say, irritabilities) in growing plants; and that, whether a plant grows vertically upwards or downwards or horizontally, depends on the individual and highly sensitive constitution of the plant in question. It is, of course, true that those who seek for mechanical explanations of growth curvatures might be able to find such a one for transverse geotropism. But when Frank's conception has once been seized such views are less and less acceptable; and, judging from my own experience, I cannot doubt that Frank's work deserved to have a powerful effect in preparing the minds of physiologists for a just view of irritability.

The belief in transverse geotropism received interesting support from Vöchting's work ("Die Bewegung der Blüthen und Fruchte," 1882) on the movement of certain flowers which retain a horizontal position under the influence of gravitation.

Frank's views, it may be added, were accepted by my father and myself in our "Power of Movement," in which the term diageotropism was proposed, and has been generally accepted, for transverse geotropism. Nevertheless, though Frank was undoubtedly right, his views were strongly opposed at the time. He held similar views on the effect of light, believing that the power possessed by leaves of placing themselves at right angles to the direction of incident light must be considered as a new type of heliotropic movement, transverse or diaheliotropism. Frank's views were criticized and opposed by De Vries (Sachs's *Arbeiten*, 1872), who, by means of experiments carried out in the Würzburg Laboratory, tried to show that Frank's results can be explained without having resort to new types of geo- or heliotropism. De Vries believed, for instance, that a leaf may be apheliotropic and apogeotropic, and that its horizontal position under vertical illumination is due to a balance struck between the opposing tendencies, one of which calls forth an upward, the other a downward curvature.

The same point of view occurs again in Sachs's paper on "Orthotrope and Plagiotrope Plant-members" (Sachs's *Arbeiten*, 1879). Sachs holds to the opinion that Frank's theory is untenable, that it is upset by De Vries, and that the oblique or horizontal position is to be explained as the result of a balance between opposing tendencies.

In a paper published the following year, 1880 (Journal Linn. Soc.), I attempted to decide between the opposing views. My experiments proved that at least certain leaves can place themselves at right angles to the direction of incident light when there is no possibility of a balance being struck. The outcome of my experiments was to convince me that Frank's views are correct—namely, that the quality of growth called transverse heliotropism does exist.

This view was accepted by my father in the "Power of Movement." The conclusions of Vöchting, in the *Bot. Zeitung*, 1888, and Krabbe in Pringsheim's *Jahrbücher*, 1889, vol. xx., are on the same side of the question.

The general result of these confirmations of Frank's conception has been to bring to the front a belief in the individuality of the plant in deciding what shall be the effect of external conditions. Such a view does not necessarily imply irritability in a strict sense, for Frank himself explained the facts, as we shall see, in a different way. But it could not fail to open our eyes to the fact that in growth-curvatures, as in other relations to environment, external changes are effective as guides or signposts, not as direct causes.

Frank saw clearly that plants may gain such various aptitudes for reacting to light and gravitation as best suit their modes of life.

In stating this view, he refers to the influence of the "Origin of Species," which had shown how any qualities useful to living things might be developed by natural selection. Frank described the qualities thus gained under the term *polarity*. He supposed that the cell-membranes of a transversely heliotropic leaf (for instance) were so endowed that a ray of light striking it obliquely from base to apex produced an increase of growth on the side away from the light; while a ray oblique from apex to base caused a reverse movement. The polarity-assumption of Frank is a purely gratuitous one, and, if strictly interpreted, hardly tends to bring growth-curvatures into harmony with what we know of the relation of life to environment.

It will no doubt appear to be a forcing of evidence if, after such a statement as the last, I still claim for Frank that he led the way to our modern view of irritability. I can, of course, only judge of the effect of his writings on myself, and I feel sure that they prepared me to accept the modern views. It must also be insisted that Frank, in spite of his assumption of polarity, seems to have looked at the phenomena in a manner not very different from ours of the present day. Thus, he compares the action of gravitation on plants to the influence of the perception of food on a chicken. He speaks, too, of custom (Journal Linn. Soc., 1880, p. 91), or use, building up the specialized "instinct" for certain curvatures. These are expressions consistent with our present views, and I think that Vines ("Physiology") is perfectly just in speaking of Frank's belief in different kinds of irritability, although in so judging he may perhaps have followed equity rather than law.

One of the chief bars to the development of our present views on irritability was the fact that simple growth in length is influenced, and markedly influenced, by differences in illumination. Plants grow more quickly, *cæteris paribus*, in darkness than in light. With this fact to go on, it was perfectly natural that simple mechanical explanations of heliotropism should be made. De Candolle, as is well known, explained such curvatures by the more rapid growth of the shaded side. Thus it

Digitized by Google

came about that heliotropism was discussed, for instance, in Sachs's "Text-book," edit. 4, 1874, under the same heading as the influence of light on rectilinear growth.

Shortly afterwards, in 1876, a pupil of Sachs—Müller-Thurgau—published ("Flora") a research carried out in the Würzburg Laboratory, which is of some importance. In the introductory remarks he wrote:—"It has been hitherto supposed that heliotropic curvatures depend on a difference in intensity of illumination on the two sides. Sachs came to a different opinion in his work on geotropism: he found himself compelled to believe that in heliotropic, just as in geotropic curvatures, it is not a question of different intensities on opposite sides, but rather that heliotropic effect depends on the direction of the light."[1]

Müller's research gave weight to this union of geo- and heliotropic effects by showing a number of resemblances in the manner and form of the two curvatures. Again, when it was found[2] that apheliotropic organs are influenced by light and darkness in precisely the same manner as positively heliotropic ones, it became clear that the mechanical explanation of De Candolle was untenable for negatively heliotropic organs, it might still no doubt be upheld for positively heliotropic organs, but, as a matter of fact, it was not so upheld. There was a tendency to unify our view of growth-curvatures, and the union of the two forms of heliotropism gave strength to the movement. Nor was this all; when it became clear that light did not produce heliotropic curvatures by direct mechanical effect, it was natural to remember that gravitation has none either; we cannot point to any reason (except the crudest ones) why the lower side of a horizontal stem, or the upper side of a horizontal root, should grow the faster for the direct effects of gravitation. That being so, light and gravitation could be classed together as external agencies acting, not directly, but in some unknown indirect manner. I do not imply that such a result followed immediately, but that the line of research above alluded to helped in some degree to lead the way to a belief in growth-curvatures as phenomena of irritability.

When my father was writing our book, "The Power of Movement in Plants" (1880), in which he adopted to the fullest extent a belief that growth-curvatures are phenomena of irritability, the only modern statement of such a view which he could find was in a passage by Sachs (*Arbeiten*, ii., 1879, p. 282), where he writes that "The living material of plants is internally differentiated in such a way that different parts are supplied with specific energies resembling those of the sensory-nerves (*Sinnesnerven*) of animals. Anisotropy in plants fulfils the same purpose as do sense-perceptions in animals."

The idea of irritability as applied to growth-curvatures is expressed with sufficient clearness in "The Power of Movement." Thus, for the case of geotropism we wrote (p. 521):—"Different parts or organs on the same plant, and the same part in different species, are thus excited to act in a widely different manner. We can see no reason why the attraction of gravity should directly modify the state of turgescence and subsequent growth of one part on the upper side, and of another part on the lower side. We are therefore led to infer that both geotropic, apogeotropic, and diageotropic movements, the purpose of which we can generally understand, have been acquired for the advantage of the plant by the modification of the ever-present movement of circumnutation. This, however, implies that gravitation produces some effect on the young tissues sufficient to serve as a guide to the plant." A similar view is given for heliotropism. It should be noted that the essence of the view—namely, that light and gravitation act as guides or landmarks by which the plant can direct itself—can be held without a belief in circumnutation.

In Pfeffer's admirable "Pflanzenphysiologie," 1881, the conception of stimulus and reaction is fully given, and is applied, among other cases, to that of heliotropism and geotropism. Pfeffer states clearly, and without reserve or obscurity, the view that light and gravitation act as stimuli or releasing forces, in manners decided by the organization of the plant. Pfeffer seems to me to be the first writer who has treated the subject fully and consistently.

In Sachs's "Vorlesungen" (1882), a view similar to that briefly sketched in his paper of 1879 is upheld. Geotropism and heliotropism are described as *Reizerscheinungen, i.e.* phenomena of stimulation. The phenomena in question are described under the heading Anisotropy, a word which expresses, according to Sachs (p. 855), "the fact that different organs of a plant under the influence of the same external forces assume the most varied directions of growth." In another passage (p. 859) he states that the anisotropy of the different organs "is nothing else than the expression of their different irritability to the influence of gravity [and] light, &c."

Vines ("Physiology of Plants"), who has recently (1886) summarized the evidence on growth-curvatures, and whose researches on kindred subjects entitle his opinion to respect, accepts fully the view that gravitation, light, &c., act as stimuli.

It is not necessary to trace the subject further, the views under discussion being now well-recognized canons of vegetable physiology.

I cannot, however, omit to mention Pfeffer's (*Tübing. u. Untersuchungen*, vol. i.) brilliant researches on the chemotaxis (irritability to certain reagents) of low organisms, such as antherozoids and bacteria. To take a single instance, Pfeffer showed that the antherozoids, in responding to the effect of malic acid, follow precisely the same law that in animals correlates the strength of stimulus and amount of effect. This result, although it has no direct connection with growth-curvatures, is nevertheless of the highest importance in connection with the general question of vegetable irritability.

Nor can I omit to mention the ingenious reasoning by which Noll (Sachs's *Arbeiten*, vol. ii. p. 466) localized the seat of irritability in a vegetable cell. He points out how in acellular plants, such as Caulerpa or Derbesia, the flowing protoplasm may travel from positively geotropic root to apogeotropic stem, and he argues from this that the motile endoplasm cannot be the seat of specific irritability. The flowing plasma, which is always changing its position with regard to external forces, must be as fully incapacitated from responding to them as though the plant were turning on a klinostat. It follows from this that it must be the stationary ectoplasm which perceives external change. From a different point of view, this is what we should expect—we should naturally suppose that the part which regulates the growth of the membrane, and therefore the curvature of the cell, should be the irritable constituent of the cell contents.

In attempting to trace the history of the establishment of growth-curvatures as phenomena of irritability, I have been forced to confine myself to a slight sketch. I have found it impossible to give a full account of the course of research on the subject. I have given an account of some of the halting-places in the journey of thought, but not to the manner in which belief has travelled from stage to stage. Far greater knowledge than mine would be required to compile such an itinerary.

Mechanism.

The first step in advance of Hofmeister's views was the establishment that the curvatures under consideration are due to unequal growth—that is to say, to an excess of longitudinal growth on the convex than the concave side. It is not, however, easy to say how far Hofmeister had this idea, for it, in fact, depends on how we define "growth." Hofmeister knew, of course, that the convex side of a curved shoot was longer than it had been before the curvature occurred; this is a mathematical necessity. But he also made out the important point that the concave side increases in length during the curvature. These permanent elongations he must have known to be growth, but his attention was directed to what is, after all, the more important point—namely, *why* it was that unequal elongation took place.

Sachs, in his "Experimental-Physiologie," held that growth-curvatures are due to unequal growth. In his "Text-book" (1874), English translation, 1882, p. 853, the author, referring to Hofmeister's work, says:—"I pointed out that the growth of the under surface of an organ capable of curving upwards was accelerated, and that of the upper surface retarded; I did not at the time express an opinion as to whether these modifications of growth were due to an altered distribution of plastic material or to a change in the extensibility of the passive layers of tissue." Frank's already-quoted paper made valuable contributions to the subject. He showed that the epidermic cells on the convex side of the root are longer than those on the concave side—that is, they have grown more; he explained apogeotropic curvatures in precisely the same way. He showed, moreover, that the

[1] In his "Vorlesungen," p. 854, Sachs states that he wrote Müller-Thurgau's introduction.

Digitized by Google

sharp curve close to the tip of a geotropic root, and the long gradual curve of an apogeotropic shoot, are necessary consequences from the manner in which growth is distributed in these parts. He demonstrated that rectilinear growth and geotropic curvature require the same external conditions; that, for instance, a temperature low enough to check growth also puts a stop to geotropism.

The distribution of longitudinal growth, which produces geotropism, was afterwards studied by Sachs (*Arbeiten*, i. p. 193, June 1871), who thoroughly established the fact that the convex side grows faster, while the concave side grows slower, than if the organ had remained vertical and uncurved.

These facts are of interest in themselves, but they do not, any more than Frank's results, touch the root of the matter. Until we know something of the mechanics of rectilinear growth, we cannot expect to understand curves produced by growth. The next advance in our knowledge did, in fact, accompany advancing knowledge of rectilinear growth. It began to be established, through Sachs's work, that turgescence is a necessary condition of growth. A turgescent cell is one which is, as it were, over-filled with cell sap; its cell-walls are stretched by the hydrostatic pressure existing within. In osmosis, which gives the force by which the cells are stretched, a force was at hand by which growth could be conceived to be caused. The first clear definition of turgor, and a statement of its importance for growth, occurs in Sachs's classical paper on growth (*Arbeiten*, p. 104, August 1871).

As soon as the importance of turgor in relation to growth was clearly put forward, it was natural that its equal importance with regard to growth-curvatures should come to the fore, and that increased growth on the convex side (leading to curvature) should be put down to increased internal cell-pressure in those tissues. In the fourth edition of Sachs's "Lehrbuch" (1874), Eng. trans., 1882, p. 834, such a view is tentatively given, but the author saw very clearly that much more evidence was needed before anything like a conclusion as to the mechanism of movement could be arrived at. The difficulty which faced him was not a new one—in a slightly different form it had occurred to Hofmeister—the question, namely, whether the curvatures of acellular and multicellular organs depend on the same or on different causes. If one explanation is applicable to both, then we must give up as a primary cause any changes in the osmotic force of the cells. For no change in the pressure inside a cell will produce a curvature in that cell, whereas, in a multicellular organ, if in the cells in one longitudinal half an increase of osmotic substances takes place, so that the cell-walls are subject to greater stretching force, curvature will take place.

On the other hand, if the cause of bending of acellular and multicellular organs is the same, we must believe that the curvature takes its origin in changes in the cell-walls. In an acellular organ, if the cell-membranes yield symmetrically to internal pressure, growth will be in a straight line; if it yields asymmetrically it will curve. Thus, if the membrane along one side of a cell becomes more or less resisting than the rest of the membrane, a curvature will result.

If we are to apply strictly the same principle to acellular and multicellular organs, we must suppose that the whole organ curves, because each individual cell behaves like one of the above-described free cells, the curvature of the whole resulting from the sum of the curves of the separate cells. This was Frank's view, and it also occurs in Sachs's "Text-book" (1874), Eng. trans., 1882, p. 842.

Are we bound to believe that the mechanism of acellular and multicellular curvatures is so strictly identical as Frank supposed? In the first place, it is not clear why there should be identity of mechanism in the movements of organs or plants of completely different types of structure. The upholders of the identity chiefly confine themselves to asseveration that a common explanation must apply to both cases. I believe that light may be thrown on the matter by considering turgescence, not in relation to growth, but in regard to stability of structure.

An acellular organ, such as the stalk of the sporangium of Mucor, owes its strength and stiffness to the tension between the cell contents and the elastic cell-wall, but it does not follow from this that in multicellular organs strength and stiffness are due to the sum of the strength of its individual cells. Indeed, we know that it is not so: the strength of a multicellular organ depends on the tension between pith and cortex. It is, in fact, a model of the single cell; the pith represents the cell-sap, the cortex the cell-wall. Here, then, it is clear that the function performed by the cell-wall in one case is carried out by cortical tissues in the other. If this is the case for one function, there is no reason why it should not hold good in another, viz. the machinery of movement.

If we hold this view that the cortex in one case is analogous with a simple membrane in the other, we shall not translate the unity of acellular and multicellular organs so strictly as did Frank. Indeed, we may fairly consider it harmonious with our knowledge in other departments to find similar functions performed by morphologically different parts. The cortex of a geotropic shoot would thus be analogous with the membrane of a geotropic cell in regard to movement, just as we know that these parts are analogous in regard to stability.

In spite of the difficulties sketched above, one writer of the first rank, namely, H. de Vries, has upheld the view that growth-curvatures in multicellular organs (*Bot. Zeitung*, 1879, p. 835), are due to increased cell-pressure on the convex side; the rise in hydrostatic pressure being put down to increase of osmotic substances in the cell-sap of the tissues in question. Such a theory flowed naturally from De Vries's interesting plasmolytic work (*ibid.* 1877, p. 1). He had shown that those sections of a turgescent shoot which were in most rapid growth show the greatest amount of shortening when turgescence is removed by plasmolysis. This was supposed to show that growth is proportional to the stretching or elongation of the cell-walls by turgor. Growth, according to this view, consists of two processes: (1) of a temporary elongation due to turgescence, and (2) of a fixing process by which the elongation is rendered permanent. De Vries assumed that where the elongation occurred, its amount must be proportional to the osmotic activity of the cell contents; thus neglecting the other factor in the problem—namely, the variability in the resistance of the membranes. He applied the plasmolytic method to growth-curvatures, and made the same deductions. He found that a curved organ shows a flatter curve[1] after being plasmolyzed. This, according to his previous argument, shows that the cell-sap on the convex is more powerfully osmotic than that on the concave side. This again leads to increased cell-stretching, and finally to increased growth.

The most serious objection to De Vries's views is that the convex half of a curving organ does *not* contain a greater amount of osmotically active substance.[2] It must, however, be noted in the heliotropic and geotropic curvature of pulvini, there is an osmotic difference between the two halves[3]—so that, if the argument from uniformity is used against De Vries (in the matter of acellular and multicellular organs), it may fairly be used in his favour as regards the comparison of curvatures produced with and without pulvini.

It is not easy to determine the extent to which De Vries's views on the mechanics of growth-curvature were accepted. The point, however, is of no great importance, for the current of conviction soon began to run in an opposite direction.[4]

Sachs ("Lehrbuch," ed. 4, Eng. trans. p. 835) had already pointed out that attention should be directed to changes in extensibility of cell-walls as an important factor in the problem.

Wiesner, in his "Heliotropische Erscheinungen" (*Wiener Sitzungsb.*, vol. lxxxi., 1880, p. 7; also in the *Denkschriften*, 1882), held that the curvature of multicellular organs is due both to an increase of osmotic force on the convex side, and to increased ductility[5] of the membranes of the same part. He repeated De Vries's plasmolytic experiments, and made out the curious fact that in many cases the curvature is increased instead of being diminished. He attributed the result to the concave tissues being more perfectly elastic than ductile convex tissues, so that when turgescence is removed, the more elastic tissues shorten most, and, by diminishing the length of the concave side, increase the curvature.

Strasburger, in his "Zellhäute" (1882), suggested that growth-curvatures are due to increased ductility of the convex membranes, and gave a number of instances to prove that a change to a ductile condition does occur in other physiological processes, such as the stretching of the cellulose ring in Œdogonium to a

[1] Frank made similar experiments, but failed to find any diminution of curvature.

[5] Weinzierl, *Sitzungsb Wien.*, 1877, showed that strips of epidermis taken off the convex side of heliotropically curved flower-stalks of tulip and hyacinth were about twice as extensible when stretched by a small weight, 7·5 grammes, as approximately corresponding strips for the concave side.

Digitized by Google

uniform thin membrane, the branching of Cladophora, and the escape of sexual products in certain Algæ.

We now pass on to the work of two observers, Wortmann and Noll, who have devoted special attention to mechanism of curvatures. Wortmann (*Bot. Zeit.*, 1887, p. 785) started on the assumption, already several times mentioned, that the growth-curvature of acellular and multicellular organs must have a common cause. He began by testing Kohl's statement (*Bot. Hefte*, Marburg, Heft v. [I have not seen Kohl's paper]) that when the sporangiferous hypha of a Phycomyces curves apogeotropically or heliotropically, &c., there is a collection of protoplasm on the concave wall. Wortmann principally investigated the curvature discovered in Phycomyces by Errera (*Bot. Zeitung*, 1884) which can be produced by contact. When the hypha is touched with a glass filament or with a platinum wire, or by allowing a speck of indian ink to dry on it, it curves over towards the touched side. The hypha is so highly sensitive to contact that it curves in from three to six minutes; it is clearly a growth-curvature, for it only occurs in the part of the hypha which is growing. In curvatures thus produced, as well as in apogeotropic and heliotropic curvatures, the accumulation of protoplasm on the concave side is, according to Wortmann, clearly visible, and, what is more important, the membrane becomes thicker on the concave side, sometimes twice as thick as on the opposite side of the cell. In consequence of the unequal thickening of the membranes, the cell is supposed to yield asymmetrically cell-pressure, and the necessary consequence is that the cell grows into a curved form.

In applying the same method of investigation to multicellular parts, Wortmann followed Ciesielski (Cohn's "Beiträge," 1872, p. 1), who noticed that in geotropically curved roots the cells of the concave (lower) side of the organ are much more densely filled with protoplasm than are the convex cells. Sachs ("Vorlesungen," p. 842) describes a similar state of things in the halms of grasses, and Kohl, again, in tendrils and the stems of climbing plants.

Wortmann first of all made sure that no redistribution of protoplasm could be observed in the *individual* cells of curving multicellular organs. If each cell behaved independently like a free cell, we might expect to find a collection of protoplasm on the concave wall of all the constituent cells of a curving shoot. But this is not the case. Nor at first could any microscopic differences be made out between the concave and convex tissues of a curving shoot. But when the stimulus was made to act for a long time, differences were apparent. A young Phaseolus plant was placed so that the epicotyl was horizontal and was forced to grow in the horizontal direction by a thread attached to the end of the stem, passing over a pulley and fastened to a weight. Here the geotropic stimulus could continue to act for 24–36 hours, and under such conditions a marked change in the tissues was visible. The cells of the cortex on the upper side became densely filled with protoplasm, while the lower cortical cells were relatively poor in protoplasmic contents. The same changes in the membranes occur as those noticed in Phycomyces—that is to say, the walls of the cortex on the upper side are very much thicker than those on the lower side.[1]

Since the walls of the cortical cells have become more resisting on the upper than on the lower side, then (assuming the osmotic expanding force to be the same in both cases) the growth will be quicker on the lower side, and the shoot will curve upwards. Wortmann states that his observations account for the fact that the convex side grows quicker, not merely than the concave, but than a normal unbent shoot. But he does not seem to have compared the thickness of the convex cell-walls with the normal, although he states that they are poorer in protoplasm than is usual, and from this it may, according to his views, be perhaps assumed that the membranes are abnormally thin.

Wortmann points out that his views account for two well-known features in growth-curvatures, viz. the *latent period* and the *after-effect*. If a curvature can only occur when a difference in structure of cell-walls has arisen, it is certainly natural that some time should occur before the curvature is apparent. I do not lay much stress on this part of the subject, as I feel sure the whole question of latent period needs further investigation. With regard to after-effect it is true that Wortmann's views account for the continuance of curvature after the stimulus has ceased to act.

Wortmann attaches great importance to another point in his theory, which, could it be established, would be of the greatest interest, and would unite under a common point of view, not only acellular and multicellular organs, but also naked protoplasm, *e.g.* the plasmodia of myxomycetes. The view in question was tentatively suggested by Sachs ("Lehrbuch," 1874; Eng. trans., 1882, p. 841), and mentioned by Pfeffer ("Pflanzenphysiologie," ii. p. 331) in a similar spirit. The apogeotropic curvature of a Phycomyces-hypha is supposed to be due to the unequal thickening of the membrane on the upper and lower sides, and this to be due to the migration of protoplasm from the lower to the upper side of the cell. In the same way in a multicellular organ the protoplasm is supposed to migrate from the lower cortex and pith to the upper cortex and pith, such migration being rendered possible by the now generally admitted intercellular protoplasmic communication. Thus the apogeotropism of a cell or a multicellular part would be due to the apogeotropism or tendency to migrate vertically upwards of the protoplasm. There are great difficulties in the way of accepting this attractive theory.

Noll (Sachs's *Arbeiten*, 1888, p. 530) states that when a curved Phycomyces-hypha, in which protoplasm has accumulated in the upper (concave) side, is reversed so that the mass of protoplasm is below, it does not migrate upward again, as might be expected. Moreover, he points out that in Nitella and in Bryopsis the circulating protoplasm continues in movement, and does not accumulate in any part of the cell. Lastly, there seems, as Noll points out, a difficulty in believing in the migration of protoplasm through the very minute pores by which the plasma strands pass from cell to cell. There seems much probability in Noll's view that the plasmic strands only serve for the passage of impulses, or molecular changes, and that they consist of ectoplasm alone, not of the endoplasm which Wortmann describes as the migratory constituent of the cell.

Wortmann's theory has been criticized by Elfving (*Finska Vet. Soc. Förhand.*, Helsingfors, Bd. xxx., 1888). The essence of Elfving's paper is that appearances similar to those described by Wortmann can be produced by curvatures not due to stimulation. Thus, when Phycomyces is made to grow against a glass plate it is mechanically forced to bend. Yet here, where there is no question of stimulation, the plasma collects along the concave side of the cell. Elfving concludes that the visible changes are the result and not the cause of the curvature. Elfving also produced curvature in Phaseolus by bending the apex of the plant towards its base and tying in that position. Under these conditions the convex side of the shoot showed the changes described by Wortmann in geotropic plants. Here again Elfving gives reason to believe that the thickening of the cell-walls is a result, not of curvature, but of strain mechanically produced. When a plant is prevented from executing an apogeotropic movement it is clear that a longitudinal strain is put on the upper (concave) side. But the longitudinal strain in Elfving's plants is on the convex side. Therefore, if, as Elfving believes, the visible changes are due to strain, they should, as they do, occur on the convex side in his experiments, on the concave in Wortmann's.

Wortmann replied in the *Bot. Zeitung*, 1888, p. 469, and attempted to explain how Elfving's results might be explained and yet his own theory hold good. The reply is by no means so strong as the criticism, and it must be allowed that Elfving has seriously shaken Wortmann's argument.

Somewhat similar criticisms have been made by Noll (Sachs's *Arbeiten*, 1888, p. 496). In the acellular plants, Derbesia and Bryopsis, Noll studied growth-curvatures, and was quite unable to detect any thickening of the concave cell-walls, except when the curvatures were very sudden, and in these cases the result could equally well be produced by mechanical bending.

Noll further points out what is undoubtedly a fault in Wortmann's theory—namely, that he explains the retardation on the concave rather than acceleration on the convex side. This criticism is only partially just, for though Wortmann's description only shows a *relative* thinness of the walls on the convex side, yet it is clear he believed there to be an absolute diminution of resisting power on that side.

Noll's experiments with grass halms show clearly that acceleration of growth on the convex side is the primary change, rather than retardation along the concave half. When the halms are fixed in horizontal glass tubes, so that they are stimulated but unable to bend, the lower half of the pulvinus forms an irregular out-growth, increasing radially since it is not able to increase longitudinally.

[1] Both protoplasmic change and thickening of cell-walls occur to some extent in the pith.

Digitized by Google

A similar argument may be drawn from Elfving's experiments. He found that the pulvini of grass halms placed on the klinostat increase in length. This experiment shows incidentally that the klinostat does not remove but merely distribute equally the geotropic stimulus: also that geotropic stimulus leads to increased, not to diminished growth. The same thing is proved by the simple fact that a grass halm shows no growth in its pulvinus while it is vertical, so that when curvature begins (on its being placed horizontal) it must be due to acceleration on the convex, since there is no growth on the concave side in which retardation could occur. Noll's view is that the primary change is an increase in extensibility of the tissues on the convex side. This view he proceeded to test experimentally. A growing shoot was fixed in a vertical position, and a certain bending force was applied to make it curve out of the vertical, first to the right and then to the left. If the cortical tissues are, at the beginning of the experiment, equally resisting all round, it is clear that the excursions from the vertical to the right and left will be equal. As a matter of fact the excursions to the right and left were nearly the same, and the difference was applied as a correction to the subsequent result. The shoot was then placed horizontally until geotropic or other curvature was just beginning, when the above bending experiment was repeated. It was then found that when it was bent so that the lower side was made convex, the excursion was greater than it had been. In the few experiments given by Noll the excursion in the opposite direction (stretching of the concave side) was less than it had been, and he states that all the other experiments showed a similar result The increased extensibility of the convex side is clearly the most striking part of the phenomenon, but I fail to see why Noll takes so little notice of the diminution in the extensibility of the concave side, which is only mentioned towards the end of his paper (*loc. cit.* p. 529). Yet such a diminution is a necessary factor in the mechanism of curvature. It should be noted that results like Noll's might be obtained under other conditions of growth-curvatures. Thus if De Vries's view were the true one, and the curvature were due to difference in osmotic force on the convex and concave sides, the shoot would react differently in the two directions; for instance, the concave side would be the more easily compressed. Noll and Wortmann's explanations differ in this: the former lays the greater stress on the increased extensibility of the convex side, the latter on the diminution of that of the concave side. Again, Wortmann explains the difference in extensibility as due to differences in thickness of the cell-walls. Noll gives no mechanical explanation, but assumes that the ectoplasm has the power of producing changes in the quality of the cell-wall in some unknown way.

In the early stages of curvature, a phenomenon takes place to which Noll attaches great importance as supporting his view. When a curved organ is plasmolyzed, it suffers a diminution of curvature, as De Vries showed, but Noll [1] has proved that in the early stages of curvature a contrary movement occurs—that is to say, the curvature is increased. This seems to show that the yielding of the convex side is owing to a ductility, which prevents its holding its own against the more perfect elasticity of the concave side. But this is only the beginning of the phenomenon; as the plasmolyzing agent continues to act, a reverse movement takes place, the well-known flattening of the curvature described by De Vries. It is to me incomprehensible how in a given condition of cell-walls these results can occur in different stages of plasmolysis. I can understand one occurring when the curvature is recent, and the other, the flattening of the curve, occurring when the ductile convex parts have reacquired elasticity. The fact undoubtedly is as Noll describes it: his explanation seems to me inadequate.

We have now seen that the most acceptable theory of the machinery of these curvatures is in its main features akin to Hofmeister's, the power of elongation supplying the motive force, while the varying extensibility of the membranes determines the nature and direction of the bend.

The question now arises: Is it possible by these means to account for all the facts that must be explained? Taking the theory for which there is most to be said on experimental grounds—viz. Noll's—it will be noted that it is essentially connected with the doctrine of growth by apposition. The question, therefore, whether the apposition-theory is sufficient to account for the phenomena of ordinary growth, may be applied *mutatis mutandis* to growth-curvature. This doctrine in its original purity absolutely requires turgescence to account for the elongation of growth. The older layers, separated from the ectoplasm by the younger layers of cell-wall, can *only* be elongated by traction. Growth by intussusception does not absolutely require this force; the theory that the micellæ are separated by traction, and thus allow intercalation of fresh micellæ, is a view for which Sachs is chiefly responsible.

Since surface-growth by apposition is absolutely dependent on the traction exercised by cell-pressure, it is a fair question—how far growth is influenced by forcible elongation. Baranetzky (*Mem. Acad. St. Pét.*, v. vol. xxvii. p. 20) states that when a plant is subject to traction, as by even a small weight attached to the free end, the rate of growth is lowered. Ambronn (Pringsheim's *Jahrb.*, xii.), as Zimmermann points out in the same connection, found no increased elongation of collenchyma when stretched for some days by means of a weight. A greater difficulty is that growth may be absolutely and at once stopped by placing the growing organ in an atmosphere free from oxygen (Wieler, Pfeffer's *Untersuch.*, Bd. i. p. 189). Such treatment apparently does not diminish turgescence, yet growth stops. If the cell-walls are increasing in length by mechanical stretching, and if the turgor is not interfered with, increase in length ought to continue. The same thing applies to curvatures. Wortmann has shown (*Bot. Zeit.*, 1884, p. 705) that in an atmosphere of pure hydrogen a geotropic curvature which has begun in ordinary air cannot continue; in other words, after-effect ceases. This seems to me inexplicable on Noll's or Wortmann's theories; the convex side has become more extensible than the concave, turgescence, as far as we know, continues, yet no after-effect is observed. The same result may be gathered from Askenasy's [1] interesting experiments on the growth of roots. He showed that lowering the temperature has an almost instantaneous inhibitive effect on growth. Thus maize roots (at a temperature of 26°·6) growing at the rate of 33 divisions of the micrometer per hour, were placed in water at 5°, and absolutely no growth occurred during the following ten minutes, in which the thermometer rose to 6°·5. This result is all the more valuable because we know from Askenasy's [2] other results that the turgor, as estimated by plasmolytic shortening, is about the same whether the root is in full growth or not growing at all. This is not conclusive, for if the growing cell-walls were ductile they might shorten but little although under great pressure, whereas the non-growing cells might shorten a good deal, owing to their more perfect elasticity; [3] therefore Askenasy's plasmolytic results are not in this particular connection of great importance, except as showing that the non-growing roots were certainly to some extent turgescent.

There are other facts which make it extremely difficult to understand how surface-growth can depend on cell-pressure. Nägeli ("Stärkekörner," p. 279) pointed out that the growth of cylindrical cells which elongate enormously without bulging outwards laterally, is not explicable by simple internal pressure. An internodal cell of Nitella increases to 2000 times its original length, while it only becomes ten times as wide as it was at first. The filaments of Spirogyra become very long, and keep their original width. Nägeli found that in Spirogyra the shortening produced by plasmolysis was practically the same in the longitudinal and in the transverse direction. He therefore concluded that the growth of Spirogyra cannot be accounted for by the cell-wall being differently extensible along different axes. But it must once more be pointed out that this type of plasmolytic experiment has not the force which Nägeli ascribes to it. If the cell-wall stretched like putty in one direction and like india-rubber in the other, there might be no plasmolytic shortening in the line of greatest growth. Nevertheless, in spite of this flaw in Nägeli's argument, great elongation in a single direction remains a problem for those who believe in surface-growth by apposition.

The point of special interest is that differences in extensibility in different directions cannot be supposed to exist in a homogeneous membrane. If *any* purely physical characters can explain the facts, they must be architectural characters. That is to say, we must be able to appeal to remarkable structural differences along different axes if we are to explain the facts.

[1] The similar results obtained by Wiesner are noticed above.

[1] *Deutsch. Bot. Ges.*, 1890, p. 61. This paper contains an excellent discussion on the mechanics of growth, to which I am much indebted.

[2] *Loc. cit.* p. 71.

[3] Wiesner (*Sitz. Wien. Akad.*, 1884, vol. lxxxix.-xc., Abth. i. p. 223) showed that under certain conditions decapitated roots grow much more quickly than normal ones, yet the amount of plasmolytic shortening is less. Decapitated: growth 79 per cent.; plasmolytic shortening, 8 per cent.; normal: growth, 39 per cent.; shortening, 13 per cent.

Digitized by Google

Such structural differences do, of course, exist, but whether they are sufficient to account for the phenomena is a different question. Strasburger ("Zellhäute," p. 194) supposes that the elasticity of a cell-wall depends on the last-formed layers, and as in these the microsomes are seen arranging themselves in lines or patterns, we have a heterogeneity of structure which may or may not be sufficient.

We have now seen that it is difficult to believe, although it is not inconceivable, that the extending force of cell-turgor, combined with differences in extensibility of the membranes (depending on structural characters), may account for the phenomena of rectilinear growth. But, even if we allow that this is so, how are we to apply the same explanation to growth-curvatures? How are we to account for the rapid changes in extensibility necessary to produce geotropic or heliotropic curvatures? The influences which Strasburger and Noll suppose to act on the cell-walls and render them ductile cannot account for extensibility in one direction only. Nor does Wortmann's theory, that difference in extensibility depends on difference in thickness, meet the case completely. What we need is an increase in longitudinal, not in general extensibility. I presume that these writers might say that the excess in longitudinal extensibility is always present whether general extensibility is greater or less. In the meanwhile we must pass on to more recent researches on surface-growth by apposition.

In Strasburger's later work ("Histologische Beiträge," 1889), his views on growth have undergone considerable modification. The study of certain epidermic cells, of the folds in membranes, and the repetition of Krabbe's work on certain bast fibres, have convinced him that apposition does not account for all forms of growth. Krabbe (Pringsheim's *Jahrb.*, xviii.) showed that in full-grown sclerenchyma (*e.g.* in Oleander) local widenings occur without any such amount of thinning in the membrane as would occur if the bulging were due to stretching. The only possible explanation seems to be that there is a migration of new material into the cell-wall. Such intussusception might be, as Nägeli supposed, a flow of fluid out of which new micellæ crystallize; but it is now established that cellulose arises as a modification of protoplasm, so that it would harmonize with our knowledge of the origin of cellulose if we assume that intussusception was preceded by a wandering of protoplasm into the cell-wall. Such a state of things would render possible the regulation of longitudinal growth in the case of Nitella and Spirogyra, already alluded to, as well as in growth-curvatures. This view might also harmonize with Wiesner's theory (*Sits. Wien. Akad.*, 1886, vol. xciii. p. 17) that the cell-wall contains protoplasm as long as it continues to grow.

For the sake of brevity I content myself with the above examples: I think it will be allowed that there is a focussing of speculation from many sides in favour of "active" surface-growth —or, what is perhaps a better way of putting it, in favour of a belief that the extension of cell membranes depends on physiological rather than physical properties, that it is in some way under the immediate control of the protoplasm. We may take our choice between Wiesner's wall-protoplasm (dermatoplasm), protoplasmic intussusception as conceived by Strasburger, or the action of the ectoplasm in the manner suggested by Vines,[1] who supposes that the crucial point is a change in the motility of the protoplasm, not of the cell membrane. The latter theory would undoubtedly meet the difficulties—if we could believe that so yielding a substance as protoplasm could resist the force of turgor.

The great difficulty is, as it seems to me, that since, *e.g.* in Caulerpa, surface-growth is clearly due to stretching, as Noll has demonstrated, and since in osmotic cell-pressure a stretching force does exist, it cannot be doubted that turgor, and ordinary physical extensibility are conditions of the problem. This remains true in spite of Klebs's (*Tübingen. Untersuchungen*, ii. p. 489) curious observations on the growth of plasmolyzed Algæ, or in spite of the fact that pollen tubes may grow without turgor, in spite of the same being perhaps true of young cells filled with protoplasm (see Noll, *Würzburg. Arbeiten*, iii. p. 530). In the face of all these facts, osmotic pressure in the cell must remain a *vera causa* tending to surface-growth.

If we accept some form of "active" surface-growth, we must deal with turgor in another way, although to do so may require a violent exercise of the imagination. Are we to believe, for instance, that the function of turgescence is the attaining of mechanical strength? If we hold that cell-walls increase in area independently of turgor, we shall be forced to invent a hypothesis such as the following—which I am far from intending to uphold. It is possible to imagine that the function of the force of turgor is merely to spread out the growing membrane to its full extent, and, as it were, to make the most of it. Turgor would in this respect play the part occupied by the frame used in embroidery, making it easier to carry on the work satisfactorily, but not being absolutely necessary. When mechanical strength is gained by turgor (as in Mucor), instead of by brute strength of material, as in a tree-trunk, a great economy in cellulose is effected. If turgor played our hypothetical part of smoothing out the membrane and insuring that it shall occupy as large a space as possible, it would effect the same kind of economy.

It is not necessary to inquire how far this hypothesis accords with our knowledge of cell mechanics. It is only put forth as an example of the difficulties in which we land if we seek for a new function for turgor. We are, indeed, surrounded by difficulties; for, though the theories which are classed together as protoplasmic have much in their favour, they, too, lead us into an *impasse*.

Circumnutation.

I shall conclude by saying a few words about the theory o growth-curvatures put forward in the "Power of Movement in Plants." I can here do no more than discuss the relation of circumnutation to curvature, which is the thesis of the book in question, without attempting to enter the arena with regard to the many objections which have been raised to other parts of our work.

A distinguished botanist, Prof. Wiesner, of Vienna, published in 1881 a book, "Das Bewegungsvermögen der Pflanzen," entirely devoted to a criticism of the "Power of Movement" (p. 8). It is founded on a long series of experiments, and is written throughout in a spirit of fairness and candour which gives it value, apart from its scientific excellence, as a model of scientific criticism. The words written on the title-page of the copy presented to my father are characteristic of the tone of the book: "In getreuer Opposition, aber in unwandelbarer Verehrung." A letter printed among my father's correspondence shows how warmly he appreciated his opponent's attack both as to matter and manner. Wiesner's opposition is far-reaching, and includes the chief theoretical conclusion of the book—namely, that movements such as heliotropism and geotropism are modifications of circumnutation. Neither will he allow that this revolving nutation is the widely-spread phenomenon we held it to be. According to Wiesner, many parts of plants which do not circumnutate are capable of curving geotropically, &c.; he is, therefore, perfectly justified, from his own point of view, in refusing to believe that such curvatures are derivations from circumnutation. He points out that our method of observing circumnutation is inaccurate, inasmuch as the movement is recorded in oblique projection. This we were aware of, and I cannot but think that Wiesner has unintentionally exaggerated its inaccuracy; and that, if used with reasonable discretion, it cannot lead to anything like such faulty records as in the supposititious cases given by our critic. However this may be, Wiesner's results are perhaps more trustworthy than ours, and should receive the most careful consideration.

Wiesner's conclusions, taken from his own summaries, are as follows:—

The movement described as circumnutation is not a widespread phenomenon in plants. Stems, leaves, and acellular fungi are to be found which grow in a perfectly straight line. Some roots grow for considerable periods of time without deviating from the vertical. When circumnutation does occur, it cannot be considered to have the significance given to it in the "Power of Movement." The movements observed by Wiesner are explained by him in three different ways:—

i. As the expression of a certain irregularity in growth depending on the want of absolute symmetry in structure, and on the fact that the component cells of the organ have not absolutely similar powers of growth.

ii. As the expression of opposing growth-tendencies. Thus certain organs have inherent tendencies to curve in definite planes—for instance, the bending of the hypocotyl in the plane of the cotyledons. Wiesner believes that such tendencies, when combined with others—heliotropic, geotropic, &c.—lead to

[1] Sachs's *Arbeiten*, 1878, and "Physiology," 1886. See also Gardiner, on protoplasmic contractility, in the *Annals of Botany*, i p. 366. Pfeffer has, I think, shown that Vines's and Gardiner's theories assume the existence of too great strength in the ectoplasm. See Pfeffer in *Abhandl. der k. Sächs. Gesellsch.* xvi. 1890, p. 329.

Digitized by Google

alternate bendings in opposite directions, according as one or other of the components is temporarily the stronger.

iii. Wiesner allows that circumnutation does exist in some cases. This last class he considers a small one; he states, indeed, that "nearly all, especially the clearly perceptible circumnutations," are combined movements belonging to the second of the above categories.

Although I have perhaps no right to such an opinion without repeating Wiesner's work, yet I must confess that I cannot give up the belief that circumnutation is a widely-spread phenomenon, even though it may not be so general as we supposed.

If, then, circumnutation is of any importance, we are forced to ask what is its relation to growth-curvatures. It was considered by my father to be "the basis or groundwork for the acquirement, according to the requirements of the plant, of the most diversified movements" ("Power of Movement," p. 3). He also wrote (*loc. cit.*, p. 4):—"A considerable difficulty in the way of evolution is in part removed, for it might be asked how did all these diversified movements . . . . first arise? As the case stands, we know that there is always movement in progress, and its amplitude, direction, or both, have only to be modified for the good of the plant in relation to internal or external stimuli."

Those who have no belief in the importance of circumnutation, and who hold that movements may have arisen without any such basis, may doubtless be justified in their position. I quite agree that movement *might* be developed without circumnutation having anything to do with the matter. But in seeking the origin of growth-curvatures it is surely rational to look for a widely-spread movement existing in varying degrees. This, as I believe, we have in circumnutation: and here comes in what seems to me to be characteristic of the evolution of a quality such as movement. In the evolution of structure, each individual represents merely a single one of the units on which selection acts. But an individual which executes a number of movements (which may be purposeless) supplies in itself the material out of which various adapted movements may arise. I do not wish to imply that tentative movements are of the same order of importance as variations, but they are undoubtedly of importance as indication of variability.

The problem may be taken back a stage further; we may ask why circumnutation should exist. In the "Power of Movement" (p. 546) we wrote:—"Why every part of a plant whilst it is growing, and in some cases after growth has ceased, should have its cells rendered more turgescent and its cell-walls more extensile first on one side then on another . . . is not known. It would appear as if the changes in the cells required periods of rest." Such periods of comparative rest are fairly harmonious with any theory of growth; it is quite conceivable by intussusceptionists and appositionists alike that the two stages of elongation and fixation should go on alternately,[1] but this would not necessarily lead to circumnutation. It might simply result in a confused struggle of cells, in some of which extension, in others elongation, was in the ascendant; but such a plan would be an awkward arrangement, since each cell would hinder or be hindered by its neighbour. Perfection of growth could only be attained when groups of contiguous cells agreed to work together in gangs—that is, to pass through similar stages of growth synchronously. Then, if the different gangs were in harmony, each cell would have fair play, elongation would proceed equally all round, and the result would be circumnutation.[2] Whether or no any such origin of circumnutation as is here sketched may be conceived, there can be no doubt that it had its origin in the laws of growth apart from its possible utilization as a basis for growth-curvature.

It is, however, possible to look at it from a somewhat different point of view—namely, in connection with what Vöchting has called *rectipetality* ("Die Bewegung der Blüthen und Früchte," 1882). He made out the fact that when an organ has been allowed to curve geotropically, heliotropically, &c., and is then removed from further stimulation by being placed on the klinostat, it becomes straight again. This fact suggested to Vöchting his conception of rectipetality, a regulating power leading to growth in a straight line. It may be objected that such a power is nothing more than the heredity, which moulds the embryo into the likeness of its parent, and by a similar power insists that the shoot or root shall take on the straight form necessary to its specific character. But the two cases are not identical. The essence of rectipetality is the power of recovering from disturbance caused by external circumstances. When an organ has been growing more quickly on one side than another, the regulating power reverses this state of things and brings the curving organ back towards the starting-point. We have no means of knowing how this regulating power acts in undisturbed growth. It is possible to imagine a type of irritability which would insure growth being absolutely straight, but it is far more easy to conceive growth as normally made up of slight departures from a straight line, constantly corrected. In drawing a line with a pencil, or in walking towards a given point, we execute an approximately straight line by a series of corrections. If we may judge in such a manner by our own experience, it is far more conceivable that the plant should perceive the fact that it is not growing absolutely straight, and correct itself, than that it should have a mysterious power of growing as if its free end were guided by an external force along a straight-edge. The essence of the matter is this: we know from experiments that a power exists of correcting excessive unilateral growth artificially produced; is it not probable that normal growth is similarly kept in an approximately straight line by a series of aberrations and corrections? If this is so, circumnutation and rectipetality would be different aspects of the same thing.

This would have one interesting corollary: if we fix our attention on the regulating power instead of on the visible departures from the straight line, it is clear that we can imagine an irritability to internal growth-changes existing in varying intensities. With great irritability very small departures from the straight line would be corrected. With a lower irritability the aberrations would be greater before they are corrected. In one case the visible movement of circumnutation would be very small, in the other case large, but the two processes would be the same. The small irregular lateral curvatures which Wiesner allows to exist would therefore be practically of the same value as regular circumnutation, which he considers comparatively rare.

The relation between rectipetality and circumnutation may be exemplified by an illustration which I have sometimes made use of in lecturing on this point. A skilful bicycle-rider runs very straight, the deviations from the desired course are comparatively small; whereas a beginner "wobbles" or deviates much. But the deviations are of the same nature; both are symptoms of the regulating power of the rider.

We may carry the analogy one step further: just as growth-curvature is the continuance or exaggeration of a nutation in a definite direction, so when the rider curves in his course he does so by wilful exaggeration of a "wobble."

It may be said that circumnutation is here reduced to the rank of an accidental deviation from the right line. But this does not seem necessarily the case. A bicycle cannot be ridden at all unless it can "wobble," as every rider knows who has allowed his wheel to run into a frozen rut. In the same way it is possible that some degree of circumnutation is correlated with growth in the manner suggested above, owing to the need of regular pauses in growth. Rectipetality would thus be a power by which irregularities, inherent in growth, are reduced to order and made subservient to rectilinear growth. Circumnutation would be the outward and visible sign of the process.

I feel that some apology is due from me to my hearers for the introduction of so much speculative matter. It may, however, have one good result, for it shows how difficult is the problem of growth-curvature, and how much room there still is for work in this field of research.

[1] Strasburger, "Histolog Beiträge," p. 195, speaks of the pause that must occur after the formation of a cellulose lamella. Hofmeister, *Württemburg. Jahreshefte*, 1874, describes the growth in length of Spirogyra as made up of short intervals of rapid growth alternating with long pauses of slow growth.

[2] I purposely omit the circumnutation of pulvini.

NOTES.

THE German Leopold-Caroline Academy at Halle has conferred the degree of Doctor of Philosophy on the Director of the Royal Gardens, Kew.

MESSRS. MACMILLAN AND CO. hope to publish before Christmas a series of popular sketches in the history of astronomy from the earliest times to the present day, in the form of a

Digitized by Google

volume containing three courses of lectures on astronomical biography by Prof. Oliver Lodge, F.R.S. The work will be fully illustrated, and will bear the title "Pioneers of Science."

AT the monthly meeting of the Field Naturalists' Club of Victoria, held on July 13 last, as we learn from the Melbourne *Argus* of July 14, Messrs. Luehman and French read a note and exhibited the skin of a tree-climbing kangaroo from Northern Queensland, new to science, to which they gave the name of *Dendrolagus muelleri*. This remarkable marsupial has a body about two feet in length, with a tail somewhat exceeding two feet. The disproportion between the fore legs and the hind legs is not nearly so great as that of the ordinary kangaroo and wallaby; the toes are strong and curved, to enable it to climb tall and straight trees, on the leaves of which it exists. This tree-kangaroo is more nearly allied to the species which was discovered a few years ago in Queensland than to the two species from New Guinea. The specimen described was got from a straight tree, about ninety feet above the ground.

IN his letter on "Dredging Products" (NATURE, August 13, p. 344), Mr. Alex. Meek, writing from Shetland, gave a short *résumé* of localities where Actinotrocha has been found. As the south coast of England was not mentioned, Mr. W. L. Calderwood writes to call attention to a paper by his predecessor at the M.B.A. Laboratory, Plymouth, Mr. G. C. Bourne, published in the Journal of the Marine Biological Association, vol. i., No. 1. After mentioning the occurrence of Tornaria, Mr. Bourne goes on to say:—"Actinotrocha, the larva of Phoronis, is common. . . . Several specimens of larval Amphioxus were taken in the tow-net towards the end of October." In vol. ii. No. 1, Mr. Garstang also has a note on the occurrence of the adult Phoronis. Actinotrocha has again appeared several times during the present summer.

M. IMFELD, the Swiss engineer, who has been engaged to examine the nature of the summit of Mont Blanc for the construction there of M. Janssen's proposed Observatory, recounts in a Zürich journal the difficulties he is experiencing in his preliminary survey. M. Imfeld is staying with eight workmen and two doctors at M. Vallot's Observatory, which has an altitude of 4400 metres, and thence they proceed daily to the summit, where they work for several hours a day in the endeavour to ascertain the depth of the snow for the purpose of getting the necessary foundation for the building. M. Eiffel has expressed the opinion that the construction of an Observatory will only be possible if the snow does not exceed a depth of 12 metres. M. Imfeld states that they have encountered traces of a ridge of rock 18 to 20 metres below the summit, and covered with about 1 metre of snow. They have therefore commenced to make a series of lateral tunnels on three sides, at a distance equal to 12 metres below the summit, to ascertain if the ridge extends to that height. Progress is necessarily slow. Most of the men are suffering from *mal de montagne*. Some, however, who are engaged at M. Vallot's cabin are able to work almost as long as in the valley, and they also eat and sleep well. In spite of two coke stoves, the thermometer of the cabin never rises above zero; even ink freezes, and water boils at 83°, and they cannot properly cook meat. For a day or two they were disturbed by violent storms.

MARTINIQUE has been visited by a terrible cyclone, the most violent that has been known in the island since 1817. It lasted four hours, and was followed by an earthquake; and many lives were lost. According to the latest information received in Paris from Martinique on Monday last, the number of persons known to have perished was 340; but that did not include the sailors lost in numerous shipwrecks along the coast and at sea. Besides the persons killed, very many were injured by the falling buildings, trees, and stones. All along the coast houses were completely demolished. The town of Morne Rouge is said to be a total wreck, and Fort de France is almost entirely destroyed. Much suffering prevails among the population.

MESSRS. L. REEVE AND CO. have in preparation a new work on the British Fungi, Phycomycetes, and Ustilagineæ, by George Massee, Lecturer on Botany for the London Society for the Extension of University Teaching; a work on the British Hemiptera Heteroptera, by Edward Saunders; a new work on the Lepidoptera of the British Islands, by Charles G. Barrett; and a new work on the physiology of the Invertebrata, by Dr. A. B. Griffiths.

MESSRS. WHITTAKER AND CO. are about to publish "A First Book of Electricity and Magnetism," by W. Perren Maycock. The work is intended for the use of elementary science and art and engineering students, and general readers.

MESSRS. CASSELL AND CO. are issuing, in monthly parts, a new and revised edition of Sir R. Stawell Ball's well-known "Story of the Heavens." The first part has just been published.

THE additions to the Zoological Society's Gardens during the past week include a Common Fox (*Canis vulpes*), British, presented by Captain H. S. Tunnard; five White-eared Conures (*Conurus leucotis*) from Brazil, presented by Mrs. Arthur Smithers; four Leopard Tortoises (*Testudo pardalis*), three Angulated Tortoises (*Chersina angulata*), a Galeated Pentonyx (*Pelomedusa galeata*), a Hoary Snake (*Coronella cana*), a Robben Island Snake (*Coronella phocarum*) from South Africa, presented by the Rev. G. H. R. Fisk, C.M.Z.S.; two Alligators (*Alligator mississippiensis*) from Carolina, presented by Mr. Charles Downs; a Gold Pheasant (*Thaumalea picta* ♀) from China, presented by Mr. R. Hudson; a Pig-tailed Monkey (*Macacus nemestrinus* ♂) from Java, two Water Vipers (*Cenchris piscivora*) from North America, deposited.

SOCIETIES AND ACADEMIES.

PARIS.

Academy of Sciences, August 17.—M. Duchartre in the chair.—On a new blow-pipe, by M. Paquelin.—On "cyclic systems," by M. A. Ribaucour.—New researches on the solar atmosphere, by M. H. Deslandres. (See Our Astronomical Column. —On the enormous velocity of a solar prominence observed on June 17, 1891, by M. Jules Fényi. M. Trouvelot has previously recorded a remarkable luminous outburst that occurred on the sun on June 17. The position-angle of the group of prominences observed by M. Fényi was about 282°. At one time the velocity of one portion of the group reached the high value of about 850 kilometres per second. And another portion was elevated through about 72″ 2″ in 210 seconds—the mean velocity being at least 485 kilometres per second. It is therefore concluded from the observations that matter can be projected from the sun into space with a velocity sufficient to prevent its falling back again. —Mechanical determination of the series of atoms of carbon in organic compounds, by M. G. Hinrichs.—On the arterial system of Isopods, by M. A. Schneider.—On the growth of the shell of *Helix aspersa*, by M. Moynier de Villepoix.

Arranged for the Selection of Single Specimens, &c., with Prices. Also New Lists of Rare Minerals, Rock Specimens, Geological Apparatus, Collections, Hammers, and Microscopic Sections of Rocks.

And may be had post free on application at the Repository and Museum,

88 CHARLOTTE STREET, FITZROY SQUARE, LONDON.

SIMPLE BUT EFFECTIVE.

McLEOD'S SUNSHINE RECORDER.

This ingenious instrument, which is the invention of Prof. McLeod, F.R.S., of Cooper's Hill College, Staines, consists of a cylindrical metallic camera, opposite to the lens of which is a thin glass sphere silvered inside. The sphere is mounted on a slide provided with rack and pinion for focussing the image of the sun on the sensitised paper placed in the base. The instrument must be placed with its vertical plane in the meridian and inclined with the sphere upwards so that the axis of the camera makes an angle with the horizontal equal to the latitude of the place at which it is set up. The support is constructed to suit the latitude; the observer has merely to place the instrument in the meridian.

PRICE £6 15s.

"To the solid ground
Of Nature trusts the mind which builds for aye."—WORDSWORTH.

No. 1140, VOL. 44.] THURSDAY, SEPTEMBER 3, 1891. [PRICE SIXPENCE.

Registered as a Newspaper at the General Post Office.]

[All Rights are Reserved.

THE NEW PATENT WATKIN ANEROID BAROMETER.

Prices from £5 to £12. Also same Watch Size.

Amongst many unsolicited Testimonials the following has been received by the maker:—

EDINBURGH, May 31, 1889.

DEAR SIR,—I have just returned from a six weeks' stay at the Ben Nevis Observatory, and while there had an opportunity of testing the admirable qualities of your new "Watkin" Aneroid. The result has been most satisfactory, the extreme error noted being only about $\frac{1}{100}$ of an inch. During my stay at the Observatory the Aneroid was frequently tested by taking it down 2000 feet and then comparing it with the standard on my return. The results obtained speak volumes for the high class workmanship and great accuracy you have attained in the manufacture of this instrument.

(Signed) R. C. MOSSMAN, F.R.M.S., Observer, Scott. Met. Soc.

To be obtained of all Opticians and Wholesale Houses.

UNIVERSITY COLLEGE OF NORTH WALES (BANGOR).

SESSION 1891–92 will open on SEPTEMBER 29.

DEPARTMENTS of PHYSICS, CHEMISTRY, and BIOLOGY.

PHYSICS ..... { Professor, A. GRAY, M.A. / Demonstrator, D. M. LEWIS, M.A.

CHEMISTRY ... { Professor, J. J. DOBBIE, M.A., D.Sc. / Demonstrator, G. MACGOWAN, Ph.D. (Leipzig).

BIOLOGY ..... Professor, R. W. PHILLIPS, M.A., B.Sc.

The Classes and Laboratory Courses of this College are arranged to suit the requirements of Students of Practical Science, as well as of Students preparing for University and other Examinations. Two Years of the Three Years' Course required for Graduation in Science at the University of Edinburgh may be taken at this College, and the Lectures in Chemistry, Botany, and Zoology are recognized by the Universities of Edinburgh and Glasgow as qualifying for the Medical Degrees of those Universities. One *Annus Medicus* may be taken at this College.

The extensive Laboratories (Physical, Chemical, and Biological) are fully equipped for Study and Research.

In the Physical Department a Steam-Engine and Dynamo-Electric Machinery, &c., have been provided for the Teaching of Electrical Engineering. A Special Course has been arranged in this subject.

Laboratory Fees (per Term)

on the scale of £1 1s. for six hours a week, in each Department.

A considerable number of Scholarships and Exhibitions are open for Competition at the beginning of each Session, and several are awarded at the close of each Session on the result of the Year's work.

For full information as to Science and Arts Courses, apply for Prospectus to the REGISTRAR,

W. CADWALADR DAVIES.

Bangor, July 1, 1891.

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR.

ELECTRICAL ENGINEERING.

Prof. A. GRAY will begin, in OCTOBER NEXT, a Systematic Course of Instruction in Electrical Measurement and Practical Electricity.

The Physical Laboratory is fully equipped with a Compound Steam-engine, Dynamos, Secondary Battery, and the most approved modern Measuring Instruments for all branches of Electrical Engineering.

Laboratory Fees at the rate of £1 1s. per Term for Six Hours per Week.

Composition Fee for all College Lectures for the Session, £10.

Applications for Calendar, Prospectus, and general information to be made to

W. CADWALADR DAVIES, Secretary and Registrar.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF.

COUNTY OF MONMOUTH.

The Council of the University College of South Wales and Monmouthshire is prepared to appoint a Director of the Staff of Travelling Teachers in Technical Subjects, to be established under the provisions of the scheme of the Technical Instruction Committee of the County of Monmouth. The Stipend of the Director will be £350 per Annum.

Candidates for the post must send in their Applications, together with Testimonials and References, to the undersigned, on or before TUESDAY, SEPTEMBER 8, 1891.

For further information and for Copies of the above Scheme, apply to

IVOR JAMES, Registrar.

Cardiff, August 12, 1891.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF.

The CHAIR of GREEK is now Vacant through the Election of Prof. ROBERTS as Principal of the University College, Aberystwyth. The Council will proceed to the Appointment of the new Professor in September Next. The Stipend of the Professor will be £350 per Annum.

Applications, together with Testimonials and References, should be forwarded before TUESDAY, SEPTEMBER 8, 1891.

For further Information apply to

IVOR JAMES, Registrar.

Cardiff, August 4, 1891.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF.

The Council of the University College of South Wales and Monmouthshire is prepared to appoint a PROFESSOR OF MINING. The Stipend of the Professor will be £350 per Annum.

Applications, together with Testimonials and References, should be forwarded on or before TUESDAY, SEPTEMBER 15, 1891.

For further information, apply to

IVOR JAMES, Registrar.

Cardiff, August 12, 1891.

LIVING SPECIMENS FOR THE MICROSCOPE.

Volvox globator, Asplanchnopus myrmeles, Lacinularia socialis, Plumatella repens, Paludicella Ehrenbergi, and other beautiful specimens of Pond-life, 1s. per Tube, with Drawing and Description. Amœba, Hydra, Vorticella &c., for Students.

List Post Free.

THOMAS E. BOLTON,

FARLEY ROAD, MALVERN LINK.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF.

COUNTY OF MONMOUTH.

The Council of the University College of South Wales and Monmouthshire is prepared to appoint the following Members of a Staff of Travelling Teachers in Technical Subjects for the County of Monmouth:—

A LECTURER in CHEMISTRY and METALLURGY.
A LECTURER in GEOLOGY and MINING.

The Stipend of each Lecturer will be £200 per annum, together with Travelling Expenses.

Applications together with Testimonials and References, should be sent in not later than SATURDAY, SEPTEMBER 19, 1891, to the undersigned, from whom further information in regard to the duties of the Staff may be obtained.

IVOR JONES, Registrar.

Cardiff, August 28, 1891.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF.

COUNTY OF GLAMORGAN.

The Council of the University College of South Wales and Monmouthshire is prepared to appoint the following Members of a Staff of Travelling Teachers in Technical Subjects for the County of Glamorgan:—

A Lecturer in Mathematics and Theoretical Mechanics.
A Lecturer in Chemistry and Metallurgy.
A Lecturer in Geology and Mining.
One or Two Lecturers in Mechanical Engineering.

The Stipend of each Lecturer will be £200 per Annum, together with travelling expenses.

Applications, together with Testimonials and References, should be sent in not later than TUESDAY, SEPTEMBER 8, 1891, to the undersigned, from whom further information in regard to the duties of the Staff may be obtained.

IVOR JAMES, Registrar.

Cardiff, August 12, 1891.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF.

The Council of the University College of South Wales and Monmouthshire is prepared to appoint a LECTURER in GEOLOGY. The Stipend of the Lecturer will be £200 per Annum.

Applications, together with Testimonials and References, should be forwarded on or before TUESDAY, SEPTEMBER 15, 1891.

For further information apply to

IVOR JAMES, Registrar.

Cardiff, August 12, 1891.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE, CARDIFF.

The DEPARTMENTS OF ARTS, SCIENCE, AND ENGINEERING, and the NORMAL DEPARTMENTS FOR INTERMEDIATE AND ELEMENTARY TEACHERS, will open on MONDAY, OCTOBER 5, 1891. The Lectures and Classes are open to Men and Women.

For Prospectus, and information concerning Scholarships, &c., apply to

IVOR JAMES, Registrar.

University College, Cardiff, August 11, 1891.

THE AGRICULTURAL COLLEGE, ASPATRIA.

PRINCIPAL—DR. H. J. WEBB, B.Sc.

Thorough practical and scientific Training in Agriculture. Preparation for the Colonies. Students gained the First, Third, and Fourth Scholarships of the Royal Agricultural Society, 1888; First in Agriculture Junior Scholarships, 1889; First in Agriculture Senior Scholarships, 1892.

Digitized by Google

UNIVERSITY COLLEGE, NOTTINGHAM,

ENGINEERING DEPARTMENT.

Professor, WILLIAM ROBINSON, M.E., Assoc.M.Inst.C.E.,

Session 1891–92 begins on MONDAY, OCTOBER 5

Courses of Technical Instruction extending over three years are arranged for boys who have just left school and intend to take up Electrical, Mechanical, or Civil Engineering. These include Drawing Office, Laboratory and Workshop Practice, and Classes in Engineering, Mathematics, Physics, Chemistry, and Metallurgy.

The Mechanical Workshops are completely equipped with tools both in wood and iron also forge and foundry. Instructors give special attention to Students in the various branches of Mechanical Engineering. Special facilities are offered to Students in Electrical Engineering—Electrical Laboratories including New Dynamo Room with Phœnix Dynamo, driven by Atkinson Cycle Gas-Engine, and specially fitted for Experimental Purposes Technical Instruction in Electric and Magnetic Measurements, Dynamo-testing, &c., and Students take charge of Brush-Lighting Dynamo, trim Arc Lamps, &c., &c.

Several Scholarships and Exhibitions are offered.

For Prospectus and Fees (which are exceptionally low) apply to the SECRETARY.

THE MASON COLLEGE, BIRMINGHAM.

SESSION 1891–92.

FACULTIES OF ARTS AND SCIENCE.

The NEXT SESSION COMMENCES on WEDNESDAY, SEPTEMBER 30, 1891

A SYLLABUS, containing Full Information as to the various Courses of Instruction, Lecture Days and Hours, Fees Entrance, and other Scholarships, &c., is published by Messrs. CORNISH, New Street, Birmingham, Price 6d.; by Post, 8d.

Further Particulars may be obtained on Application to the SECRETARY at the College.

R. S. HEATH, Principal.
GEO. H. MORLEY, Secretary.

THE VICTORIA UNIVERSITY.

The following Examinations will be held at OWENS COLLEGE (MANCHESTER), UNIVERSITY COLLEGE (LIVERPOOL), and YORKSHIRE COLLEGE (LEEDS), in SEPTEMBER.

AN ENTRANCE EXAMINATION IN ARTS (introductory to the Faculty of Medicine) on FRIDAY, September 25, and following days.

AN ENTRANCE EXAMINATION IN ARTS (introductory to the Faculty of Music) on FRIDAY, September 25, and following days.

A PRELIMINARY EXAMINATION (introductory to the Faculties of Arts, Science, and Law) on THURSDAY, September 24, and following days.

Notice (*in writing*) of intention to be present, accompanied with a List of the subjects taken, must be sent, on or before September 9, to the UNIVERSITY REGISTRAR, from whom Conditions of Entrance, and other Particulars can be obtained.

Fees for the above Examinations must be paid on or before September 14.

Manchester, August 1891.

VICTORIA UNIVERSITY.

YORKSHIRE COLLEGE, LEEDS.

DEPARTMENT OF SCIENCE, TECHNOLOGY, AND ARTS

The Eighteenth Session begins TUESDAY, OCTOBER 6, 1891. The Classes prepare for Professions, Commerce, and University Degrees in Arts, Science, and Medicine. The Physical, Chemical, Biological, Engineering, and Leather Industries, Laboratories, and the Weaving Sheds, Dye-house, and Printing Rooms will be open daily for practical work.

The following Prospectuses may be had free from the Secretary:—

1. For Regular Day Students.
2. For Occasional and Evening Students.
3. Classes in Leather Industries.
4. Classes in Agriculture.
5. For Medical Students.

THE YORKSHIRE COLLEGE, LEEDS.

Applications are invited for the Appointment of LECTURER on GEOLOGY for one year from October 1, at a Stipend of £100 for which 20 Lectures on the Geology of Coal Mining and 30 Lectures on Geology as connected with the Agricultural Course will be required. Opportunity will be given for Extension Lecturing in Yorkshire, for which a payment of £2 per Lecture will be made. The Lecturer would be required to reside in or near Leeds during the six winter months. The Appointment will probably be renewable.

Applications will be received by the SECRETARY of the College up to SEPTEMBER 19.

FIRTH COLLEGE, SHEFFIELD.

The Council of Firth College propose to appoint an ASSISTANT DEMONSTRATOR IN CHEMISTRY, at a Salary of £100.

Session—OCTOBER to JUNE.

Applications must be sent, before SEPTEMBER 12, to the REGISTRAR, from whom further particulars may be obtained.

THE COUNTY COUNCIL FOR THE COUNTY PALATINE OF LANCASTER.

The Technical Instruction Committee of the Lancashire County Council is prepared to receive Applications for the appointment of DIRECTOR of TECHNICAL INSTRUCTION and ORGANIZING SECRETARY. The Applicant to state whether he is prepared to give the whole of his time to the duties of the Office.

Candidates must be over 25 years of age and under 50, and the elected Candidate will be expected to enter on his duties on NOVEMBER 6, 1891

Salary, £500 per Annum, with a reasonable allowance for Travelling Expenses.

The Official will not be eligible for a Pension and the appointment is to be determinable by a Six Months' Notice in writing on either side.

A Statement of the Duties will be supplied on application.

All Applications, with Testimonials, to be sent to me the undersigned before the 30th day of SEPTEMBER, 1891.

FRED. C. HULTON,
Clerk of the County Council.

County Offices, Preston, September 1, 1891.

MERCHANT VENTURERS' SCHOOL, BRISTOL.

Headmaster: J. WERTHEIMER, B.Sc., B.A., F.I.C, F.C.S.

LECTURERS:

Engineering	J. MUNRO, M.I.Mech.E.
Applied Physics	W. WILSON, M.A. (late Assistant Professor of Physics in the Heriot Watt College, Edinburgh.
Chemistry and Metallurgy	The HEADMASTER. J. LEICESTER Ph.D., F.C.S. J. B. TINGLE, Ph.D., F.C.S.

with 35 other Lecturers, Demonstrators, and skilled artisans.

Complete Courses in Mechanical or Electrical Engineering, Chemistry, Assaying, and Metallurgy, including use of Chemical, Physical, and Metallurgical Laboratories, Metal Workshop, &c. £10 10s. a year.

Special Courses for Matriculation and B.Sc. Examinations of London University.

Prospectus (Price 2*d*) on application to the Merchants' Hall, Bristol.

BALLIOL COLLEGE, CHRIST CHURCH, AND TRINITY COLLEGE, OXFORD.

NATURAL SCIENCE SCHOLARSHIPS AND EXHIBITIONS.

A combined Examination for Natural Science Scholarships and Exhibitions will be held by the above Colleges, beginning on TUESDAY, NOVEMBER 17, 1891.

Three Scholarships and Two Exhibitions will be offered, the Scholarships being worth £80 a year.

The subjects for examination will be Physics, Chemistry, and Biology, but Candidates will not be expected to offer themselves in more than two of these.

Particulars may be obtained by application to A. VERNON HARCOURT, Christ Church, Oxford.

MALMESBURY AND DISTRICT SCHOOL OF SCIENCE AND ART.

The Committee of the above School are desirous of appointing a Master of the Art School and Science Lecturer. The Central School is at Malmesbury, but the Gentleman appointed will also be required to conduct Classes in other convenient parts (Educational districts) of the Malmesbury Union.

Candidates must state experience and detailed qualifications to earn Grants under the Science and Art Department, South Kensington. Art Teacher or Art Master (3rd Grade) preferred.

Salary, £230 and railway fares.

Apply at once to HUGH C. FORRESTER, Esq., Malmesbury, Wilts.

BRITISH ASSOCIATION.

CARDIFF MEETING.

The Hon. Local Secretaries have a number of Surplus Copies of the Hand-book to Cardiff, prepared for the use of Members at the recent Meeting of the British Association.

Copies may be obtained from Mr. W. LEWIS, Duke Street, and from Mr. J. BALLINGER, Free Library, Cardiff. Price, 1*s* each (together with 3*d*. for Postage).

R. W. ATKINSON, H. W. LLOYD TANNER, } Hon. Local Secs.

9 Bank Buildings, Cardiff.

TO SCIENTIFIC GENTLEMEN.—A

young man, an abstainer, aged 22, seeks a situation as Personal Attendant to above. Trustworthy, quiet, and methodical. Would endeavour to be useful in Museum, Laboratory, or Library. No previous experience, but possesses aptitude. Kindly state Salary and Particulars to CHARLES TYRRELL, 43 Gloucester Road, Peckham, London, S.E.

SCIENCE MASTERS WANTED FOR

GOOD SCHOOLS:—(1) Chemistry, Physics, £200 Resident; Laboratory Work. (2) Chemistry, Mathematics, £160. (3) Science for South Kensington Exams., £120 Non-Resident. (4) Botany, Mathematics, £80–£100—Apply, with Testimonials, to BIVER & Co., 298 Regent Street, London.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL,

ALBERT EMBANKMENT, LONDON, S.E.

The WINTER SESSION of 1891-92 will open on THURSDAY, OCTOBER 1, when the Prizes will be distributed at 3 p.m. by Sir G. M. HUMPHRY, M.D., LL.D., F.R.S.

TWO ENTRANCE SCIENCE SCHOLARSHIPS of 125 guineas and £60 respectively, open to all first-year Students, will be offered for competition. The Examination will be held on September 26, 28, and 29, and the subjects will be Chemistry and Physics, with either Physiology, Botany, or Zoology, at the option of Candidates.

Scholarships and Money Prizes of considerable value are awarded at the Sessional Examinations, as also several Medals.

Special Classes are held throughout the year for the Preliminary Scientific and Intermediate M.B. Examinations of the University of London.

All Hospital Appointments are open to Students without charge.

The Fees may be paid in one sum or by instalments. Entries may be made separately to Lectures or to Hospital Practice, and special arrangements are made for Students entering in their second or subsequent years; also for Dental Students and for Qualified Practitioners.

A Register of approved Lodgings is kept by the Medical Secretary, who also has a List of local Medical Practitioners, Clergymen, and others who receive Students into their houses.

Prospectuses and all particulars may be obtained from the Medical Secretary, Mr. GEORGE RENDLE.

G. H. MAKINS, Dean.

GUY'S HOSPITAL MEDICAL SCHOOL.

The WINTER SESSION begins on THURSDAY, OCTOBER 1.

The Hospital contains 695 Beds, of which 500 are in constant occupation. Special Classes are held for the M.B. Camb. and Lond., the F.R.C.S. Eng., and other Higher Examinations.

APPOINTMENTS.—All Hospital Appointments are made in accordance with the merits of the Candidates, and without extra payment.

ENTRANCE SCHOLARSHIPS in September 1891.—Two Open Scholarships in Arts, one of the Value of 100 Guineas, open to Candidates under 20 Years of Age; and one of 50 Guineas, open to Candidates under 25 Years of Age. Two Open Scholarships in Science, one of the Value of 125 Guineas, and another of 50 Guineas, open to Candidates under 25 Years of Age.

PRIZES are awarded to Students in their various years, amounting in the aggregate to more than £450.

DENTAL SCHOOL.—A Dental School attached to the Hospital affords to Students all the instruction required for a Licence in Dental Surgery.

COLLEGE.—The Residential College accommodates about Fifty Students in addition to the Resident Staff of the Hospital. There is in it a large Dining Hall, with Reading Rooms, Library, and Gymnasium for the use of the STUDENTS' CLUB.

For Prospectus and further information apply to the Dean, Dr. PERRY, Guy's Hospital, London, S.E.

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL.

The WINTER SESSION, 1891-92, will commence on THURSDAY, OCTOBER 1, when an Introductory Address will be delivered by Dr. WM. DUNCAN, F.R.C.S.

TWO ENTRANCE SCHOLARSHIPS (value £100 and £60) will be open for competition on September 29 and 30.

The School Buildings have been recently enlarged, comprising new Theatre, Library, Physiological Laboratory, Materia Medica Museum, Students' Room, and Luncheon Room.

Besides Scholarships and Prizes, there are annually EIGHTEEN RESIDENT Hospital Appointments open to Students.

The Composition Fee for the whole Medical Curriculum is 100 Guineas Special provision is made for Dental Students and for Candidates for the Preliminary Scientific (M.B.) Examination.

The Residential College adjoins the Hospital, and provides accommodation for thirty Students.

Prospectuses and all particulars may be obtained from the Resident Medical Officer at the Hospital, or from

A. PEARCE GOULD, Dean.

GUY'S HOSPITAL.

ENTRANCE SCHOLARSHIPS.

TWO OPEN SCHOLARSHIPS in ARTS (100 Guineas and 50 Guineas), and TWO OPEN SCHOLARSHIPS in SCIENCE (125 Guineas and 50 Guineas), are offered for Competition on THURSDAY, SEPTEMBER 24, and the two following Days.

For further Particulars, apply to the DEAN.

GUY'S HOSPITAL.

PRELIM. SCIENTIFIC (M.B. LOND.).

Classes are held throughout the Year. Chemistry—Mr. GROVES, F.R.S., and Mr. WADE, B.Sc.: Exp. Physics—Prof. REINOLD, F.R.S.; Biology—Mr. BEDDARD, F.R.S. (Ed.), and Dr. CAMPBELL.

Fee 18 Guineas, with special instruction for the January Examination.—Apply to the DEAN.

POND LIFE.—Stephanoceros Eichornii, Floscularia campanulata, Melicerta ringens, Janus, Polyzoa, &c. 1s. per Tube, Post free.—J. HOOD, 50 Dallfield Walk, Dundee.

SCIENTIFIC WORKS ON SALE

BY

MACMILLAN & BOWES,

CAMBRIDGE.

NATURE, Vols. 1 to 41 (April 1890), complete with all the Supplements, Portraits, &c. 14 Vols., Half bound, remainder as issued £8 8s.

QUARTERLY JOURNAL OF MICROSCOPICAL SCIENCE.—(1) The Microscopical Journal, edited by D. Cooper and G. Busk, 1841-42, 2 Vols.; (2) Transactions of the Microscopical Society, 1844-52, 3 Vols.; (3) Quarterly Journal of Microscopical Science, edited by E. Ray Lankester and G. Busk. *First Series*, 8 Vols., 1853-60; *New Series*, Vols. 1 to 10. 1861-70; 23 Vols., uniformly bound in Half-red Morocco, £25. *Fine Copy.*

GREENWICH OBSERVATORY.—Observations, 1836 to 1880. 45 Vols., 4to, Cloth. £7 7s.

GREENWICH OBSERVATORY.—Magnetical and Meteorological Observations, 1840-47, 7 Vols.; Results of Observations, 1859-64, 1866-80, 21 Vols. In all, 28 Vols. £2 2s.

POULKOVA.—Observations publiées par Otto Struve. Vols. 1 to 7, 9, and Supplement, 11. 9 Vols. and 1 Part. St. Pétersbourg, 1869-79. £3 3s.

LIOUVILLE, J.—Journal de Mathématiques pure et appliquées. 1st Series, Vols. 1 to 20. 16 Vols. in 8, Half-calf, remainder in Parts. 1836-45. £9 9s.

GIORNALE DI MATEMATICHE, publicato per cura dei Prof. Battaglini, Janni, e Trudi. Vols. 1 to 8, 1863-70. Bound into 2 Vols., Half-calf. £2 2s.

MONTUCLA.—Histoire des Mathématiques. Nouvelle édition, considérablement augmentée, et prolongée jusque vers l'époque actuelle. 4 Vols., 4to. 1799-1802. £6 15s.

A most valuable work for the History of Mathematics. This, *the best edition*, was edited and completed by Lalande. *A Fine Copy.*

ARCHIMEDIS OPERA. 2 Vols., Folio. 1544. 30s.

The first printed edition of Archimedes, with the text in Greek and Latin. The Greek text, slightly water-stained, is bound in vellum; the Latin text in half-calf.

EUCLIDE MEGARENSE PHILOSOPHO, ridotto per Nicolo Tartalea. Vinegia, 1543. 30s. Water-stained, with writing on title: otherwise a fine copy of the very scarce folio edition of Tartalea's translation.

PAPPI ALEXANDRINI MATHEMATICAE COLLECTIONES A FREDERICO COMMANDINO IN LATINUM CONVERSAE ET COMMENTARIIS ILLUSTRATAE. FOLIO. Vellum, 1660. 25s.

A fine copy of the second edition of Pappus.

PROCLUS.—Philosophical and Mathematical Commentaries on the first book of Euclid, &c. *Printed for the Author*, 1792. 2 Vols. in 1. 35s.

CLAPIN, A.C.—Optical Problems. 8vo. 1850. 3s.

A systematic collection of examples elucidating the various theorems of Geometrical Optics—Illumination. Direct and Oblique Reflection and Refraction, Prisms, Lenses, Aberration, Dispersion of Light, Images and Vision, Telescopes, Rainbow, &c.

DE MORGAN, A.—The Book of Almanacs, with an Index of Reference, by which the Almanac may be found for every year, from any Epoch, up to A.D. 2000, &c. 2nd (and last) edit. Cloth. 1871. 6s.

EARNSHAW, S.—The Doctrine of Germs, or the Integration of certain Partial Differential Equations which occur in Mathematical Physics. 8vo. 1881. 3s.

ELLIS, R. LESLIE [1817-59].—Mathematical and other Writings, edited by Wm. Walton. Memoir by Harvey Goodwin (now Bishop of Carlisle). Portrait. 8vo, Cloth. 1863. 12s.

Contents:—On the Foundations of the Theory of Probabilities, the Method of Least Squares, the Integration of certain Differential Equations, the Achromatism of Eye-pieces of Telescopes and Microscopes, Lines of Curvature on an Ellipsoid, Notes on Magnetism, &c., &c.

GREGORY, DUNCAN F. [1813-44].—Mathematical Writings, edited by W. Walton, with Memoir by R. Leslie Ellis. Portrait. 8vo, Cloth. 1865. 8s.

Contents:—On the Real Nature of Symbolical Algebra, the Solution of Linear Differential Equations with Constant Coefficients, Circular Sections in Surfaces of the Second Order, Solution of some Problems in Transversals, Solution of Partial Differential Equations, on the Impossible Logarithms of Quantities, Application of Algebraical Symbols to Geometry, &c., &c.

NEWMAN, F. W.—The Difficulties of Elementary Geometry, especially those which concern the Straight Line, the Plane, and the Theory of Parallels. 8vo. 1841 (pub. 8s.) 2s. 6d.

Catalogues Nos. 230 and 231 (Mathematics) free on application.

THURSDAY, SEPTEMBER 3, 1891.

THE REPORT OF THE BOARD OF TRADE COMMITTEE ON ELECTRICAL STANDARDS.

TARDILY, and in a somewhat piecemeal if not grudging fashion, some small provision has been made by Her Majesty's Government for the regulation, under the Board of Trade, of the new but vigorous and rapidly-extending industry which recent developments of electrical science have brought into existence. In no previously-existing branch of trade has the problem of settling standards of measurement been so difficult of solution, and in no other has the problem been so completely solved without trouble, expense, or intervention on the part of the Government itself. For the last twenty-five or thirty years a Committee of the British Association has laboured at the gigantic task of building up a system of units, which involved as a mere preliminary the revision of the conceptions and units of dynamics in order that these might form a basis for the definition of units for the far more complex physical quantities concerned in electricity and magnetism, quantities many of which had previously been by no means clearly apprehended, and which then received for the first time precise statement and definition.

Much of the work of the British Association Committee has been thankless, tedious, and, from its very nature, of a kind fitted to excite the cheap scorn of the self-styled "practical man," but it has made applied electricity possible, and has reacted in no slight degree on the progress of theory itself. The problem of the determination of the ohm—in other words, the process of realizing a standard of resistance according to the theoretical definition—has suggested problems to the theorist in the solution of which the theoretical investigator has been led to both direct and side-results of the very greatest value to the progress of science, and, in an unexpected manner, to the facilitation of practical applications. In no science have theory and practice been so closely connected during the last quarter of a century, and in none has the union been so markedly productive of good. By far the most interesting chapters of the history of electricity during the nineteenth century will be those that refer to its last three decades; may they chronicle a still closer alliance of the engineer and the experimenter, the electrical man of action and the mathematician! Here union is strength and dominion over the forces of Nature; disunion is waste of energy and slow progress in all that relates to the material, and therefore also to the social, advancement of the human race by means of electrical invention.

The establishment of the nucleus of an electrical standardizing laboratory in London, and the appointment towards the end of last year of a Committee to decide upon and recommend for adoption electrical standards for use in trade, testify to the great importance which the electrical industries have attained in this country in spite of the mistakes which attended their inception, and the general discouragement and disfavour with which they were received by the various interests they threatened.

The proceedings and report of the Committee have just been published in a blue-book, which contains matter of great interest to all engaged in electrical work. The vista which it opens up as regards the future operations of the standardizing laboratory may well dismay Her Majesty's Government; although no doubt due provision will ultimately be made for all its work. But of this at another time; at present we wish to direct attention to the resolutions of the Committee, which will be found in another page.

In the first place the Committee signify their adherence to the units of length, mass, and time as fundamental units, and adopt the C.G.S. system. This was only to be expected, for, after all, though some people may think that a better system could be devised if the work had to be done afresh, and they had a share in it, still collectively the body of scientific opinion is distinctly conservative, and there is little danger that any ill-advised attempt to disarrange the accepted system of theoretical and practical units will succeed.

Their third resolution, that the standard of electrical resistance should be called the ohm and should have the value 1,000,000,000 in terms of the centimetre and second in the ordinary electromagnetic system, is of great importance. It seems to settle once for all the question which has been debated over and over again, whether after a standard ohm has been realized, it will, like the standard yard or metre, be ever after the standard; or whether, if in case of variations in the physical properties of the substance, it shows an unexpectedly large divergence from the definition, a new standard ought to be constructed. Those who have assumed the former alternative have forgotten that the ohm is a derived unit, depending on the already fixed units of length, mass, and time, and that, therefore, its derivation ought to be as exact as the ever-widening resources of science can make it. For practical purposes of trade the standard fixed upon now and its copies are likely to remain undisturbed for a long time, and will probably only be corrected if there is serious alteration with time in their resistances. But the ohm will still be defined as 10^9 C.G.S. in the ordinary electromagnetic system of measurement, in which the magnetic permeability of air is assumed to be unity.

The fourth and fifth resolutions provide the definition of a practical realized ohm (1) by means of a column of mercury, (2) by comparison with the British Association unit, which it is stated may be taken as ·9866 of the ohm.

The wording of Resolution 4 strikes one as curious. The mercury column is to have a "constant cross-sectional area of 1 square millimetre." If "constant" has its ordinary sense of invariableness with time, the specification of 1 square millimetre renders it unnecessary. It has here apparently the usual sense of "uniform," that is, the section is the same at every part of the tube.

We are glad to see that the length adopted for the tube is 106·3 centimetres, instead of 106 centimetres, the round number adopted at the Paris Conference, and proposed, by the British Association Committee in 1886, to be legalized for a period of ten years. All the latest and best determinations of the ohm point to 106·3 as a convenient number very closely agreeing with the true value,

Digitized by Google

and its adoption now is probably only an anticipation of the decision which will be arrived at in a few years when the resolutions of that Conference are reconsidered.

In the adoption of a metallic working standard (announced in Resolution 5) the Committee only endorse an opinion long ago expressed by working electricians, that the mercury standards constructed in straight or spiral glass tubes are not practical instruments; they are difficult to handle, liable to breakage, and the only argument for their retention, the possible variability of metallic standards, has been shown to be almost baseless by the results of the continued and careful observation of the various metallic resistance coils deposited at Cambridge.

Passing over the resolutions which provide for copies, and multiples and submultiples of the ohm, with the remark that the long-felt want of trustworthy standards of low resistance will now at last be supplied, we come to the definition of the unit of current. Here again a theoretical definition corresponding to that of the ohm is given first; then for practical purposes it is stated "that an unvarying current which, when passed through a solution of nitrate of silver in water, in accordance with the specification attached to this report, deposits silver at the rate of 0·001118 of a gramme per second, may be taken as a current of 1 ampere." This is the most reasonable course that could have been adopted. The specification is practically one of the procedure adopted by Lord Rayleigh in his experiments on the electro-chemical equivalent of silver, and as Lord Rayleigh's absolute result was to be made the practical standard, it was right to recommend the same mode of experimenting.

Resolution 11, which defines the ampere in the case of an alternating current, was the subject of a good deal of discussion, and of some adverse comment by one of the witnesses examined on behalf of the electrical trades. The resolution states "that an alternating current of 1 ampere shall mean a current such that the square root of the time-average of the square of its strength at each instant in amperes is unity." It was pointed out by the witness referred to, and by at least one member of the Committee, that this was giving a very special meaning to the term, one, moreover, inconsistent with the obvious definition, that of the simple time-average of the current. This latter average would, in the case of most periodic machines, be simply zero, unless the currents in the alternate half-periods were commutated so as to agree in sign with those in the other halves. But in the case of such a machine as the Brush, used for lighting incandescent lamps, the definition given in the resolution would have to be used; whereas if the machine were used for electro-plating, the simple time-average would have to be employed. This would give for the same current passing through the machine, from instant to instant, two different average values. The electric lighting application of periodic machines is, however, by far the most important, and the Committee did well, perhaps, to retain what is already the generally understood sense of the word *ampere* in connection with alternating currents. It ought to be, however, clearly understood that the main application of the definition will be to the measurements of currents in electric lighting, and that generally in other cases another definition will have to be employed.

Another important discussion took place over the definition of the standard unit of "pressure." In the first place, we should like to say here that we object entirely to the use of the term "pressure" in this connection. It has come as a sort of analogue of hydraulic pressure, and it has certainly led to very erroneous notions in the minds of the general public as to the functions of electric supply-mains, and also as to electricity itself. It is a pity that so many of the present pioneers of electricity, who are also leaders of physical science, should have countenanced by their example this misuse of a scientific term. We all know how strenuously some of these gentlemen have objected to the term "tension" as in "high-tension electricity"; surely "high-pressure instruments" and "electricity supplied at high pressure" are as objectionable, if not even more misleading. The use of the term *voltage*, or some such word, in the present Report, would have avoided the endorsement which it seems to give to what we think is a most unfortunate name for a physical quantity which is not a pressure at all; and it is to be hoped that the British Association Committee (who, by the way, were represented on the Committee of the Board of Trade) may be able to prevent this phrase from being added to the many other, though generally less objectionable terms which infest the literature of electricity.

A discussion arose as to whether the definition of the volt as the "pressure which, if steadily applied to a conductor whose resistance is one ohm, will produce a current of one ampere," was sufficiently definite. There might, it was argued, be an internal electromotive force in the conductor, and the "pressure" applied to the conductor might be regarded as that applied from the outside, or actually existent between its terminals, as shown by an electrometer. For example, the conductor might be the armature of a dynamo; the difference of potential might be considerable and the resistance only a small fraction of an ohm. In such a case it is, of course, well known that the electromotive force producing the current through any part of the armature resistance, according to Ohm's law, is the total internal electromotive force of that part, *minus* the difference of potential existing between its terminals (both being taken positive), and it is the difference thus obtained that is to be regarded as the applied "pressure" of the definition. In the same way in a voltameter, the electromotive force causing the current, according to Ohm's law, would be the existent or applied difference of potential, *minus* the internal back electromotive force developed by the chemical action. There were other difficulties about the specification of the ends of the conductor and the canalization of the current, and it was therefore thought desirable to adhere to the simple form of definition given in the report. It must be admitted that the definition leaves room for legal disputes in practice, and we think that it would have been perhaps better to have introduced on these points some kind of note or specification referred to in the resolution, so as to be taken along with it in the event of any dispute about the meaning of the definition.

A further question arose as to the provision of a practical standard of electromotive force in the form of a constant cell; and it was decided, partly in deference to the expressed wish of practical electricians, that the Clark cell should be adopted for this purpose. Its electro-

Digitized by Google

motive force, within certain limits of error to be determined by a sub-committee appointed for the purpose of preparing a specification for the construction and use of the cell, is stated to be 1·433 volts at the temperature 62° F. By means of this cell and known resistances, it will be possible to calibrate instruments without the use of electrolysis, and this to many persons would be the readiest and most easily carried out method. Of course, logically speaking, the standard of electromotive force is settled when those of resistance and current are fixed, and thus, if the order of definition is adhered to, the cell does not come in. But its electromotive force having been determined by careful measurement, and found to be so constant as it is, and so consistently the same in different specimens when the mode of construction is carefully attended to, it is too valuable a standard of reference to be set aside.

A very interesting discussion took place as to the mode of preparing these cells, and on the experience of different investigators as to their behaviour. Some of the divergences stated in the discussion were probably due to the different degrees of manipulative skill possessed by the various observers. A few careful experiments with different batches of cells carried out personally by the members of the committee interested in the matter would set the question at rest, and probably entirely confirm Lord Rayleigh's marvellously consistent results.

A side-point which came out in discussion is worthy of notice. We have not in this country any legal definition of temperature, whether Centigrade or Fahrenheit. In the definition of the standard yard 62° Fahrenheit is specified, but there is nothing to tell how that temperature is to be determined. It is well known (though apparently not to some of the text-book writers on heat) that mercurial thermometers, made with different kinds of glass, while agreeing at the freezing and boiling points, agree nowhere else, and all differ more or less from the air-thermometer. In very accurate work these discrepancies become very important, and thermometers must be calibrated by means of standards, if their indications are to be of any use for comparison. Some legal definition of temperature will, ere long, have to be given, and it seems rather a pity that the Committee did not practically settle this by saying what they meant by 62° Fahrenheit.

The definition of the volt for alternating currents, embodied in Resolution 15, is, of course, a mere consequence of Resolution 11, and these two definitions taken together are specially applicable to the measurement of the power spent in lighting incandescent lamps.

We have only to note that the Committee, in Resolutions 12 and 16, adopted instruments on the principle of the balance for the measurement of currents, and on the principle of Sir William Thomson's quadrant electrometer, used idiostatically, for the measurement of differences of potential—except for large differences, when an electrometer on the principle of the balance is to be employed. Thus the beautiful electrometers invented long ago by Sir William Thomson are likely to become at last, in a modified form, Board of Trade standards of exact measurement in industrial electricity. This is by no means the only striking example which could be cited of the thoroughly practical, because thoroughly theoretical, character of the instruments invented by one who understands all sides of the difficult problem involved in the invention and construction of scientific apparatus.

No resolutions were framed by the Committee on the very important subject of the measurement of power and energy. This must, however, come to the front before very long, and will tax the resources of the standardizing laboratory and its officials, assisted, as no doubt they will be, by Committees such as this which has just reported. We congratulate the Committee on the results of its labours, and trust that the requisite Order in Council will be passed before long confirming its resolutions. The laboratory will then be able to get to work, the necessary standards which have been asked for so long will be made accessible to those engaged in the electrical industries, and some serious difficulties under which they have laboured, in supplying electric light and power to the public, will be at last removed.

THE CONGRESS OF HYGIENE.

WE print to-day a report of the important discussion in Section II. (Bacteriology) of the Congress of Hygiene, on "Immunity, Natural and Acquired":—

Dr. Roux, of the Institut Pasteur, in an introductory address, indicated the scope of the discussion. He began by saying that, in inviting a pupil of M. Pasteur to open the discussion on this subject, the Organizing Committee had reminded the Section that the great amount of interesting work which had recently been done on the subject had one point in common—namely, the attenuation of virus, and preventive inoculation, the two subjects with which M. Pasteur's name would for all time be honourably associated. With the single notable exception of vaccination, the only way of conferring immunity against any disease was the inoculation of the virus of the disease. To the old dangerous method of producing immunity by inoculation, Pasteur had added the less dangerous one of preventive inoculation by means of an attenuated virus, to which he had applied the term vaccination. The designation "attenuated" virus ought to be reserved for virus weakened without being attenuated—for example, by artificially lowering the vitality of the organisms for producing it.

Methods of Attenuation.—Two methods of attenuation had been described by M. Pasteur—namely, the prolonged exposure of a culture to air at a suitable temperature, and the passage of the micro-organisms through the bodies of different species of animals. Other methods had also been employed—for example, the action of heat, the use of antiseptics, of compressed oxygen and light.

In all cases, whatever the method employed, it was found to be necessary that the attenuation should be effected slowly and gradually; rapid attenuation rendered a virus altogether inactive without impressing on it any hereditary weakness. In whatever way the virus was prepared, it must, in order to confer immunity, be brought into direct contact with the tissues of the animal. In the early experiments the virus employed was always living; the living microbe, itself attenuated as to its virulence, was used. Another possible method of conferring immunity was the inoculation of the chemical substances produced by the micro-organisms.

Phagocytosis.—Dr. Roux next dealt with the doctrine of phagocytosis associated with the name of Dr. Metchnikoff. This observer had proved, by the study of the amœboid movement of certain cells that they possessed the power of including other cells and bodies in their substance. The phagocyte cells originated in the mesoderm. They possessed, further, the property of being able to digest the bodies which they had ingested. They were, in fact, the only cells which manifested in the human body any intracellular digestion. If the history of a bacterium in the interior of a phagocyte were followed, it would be seen that it underwent a peculiar series of alterations, very different from what took place when a microbe died in cultivating fluids. Whether a virulent virus was introduced into the bodies of animals which resisted inoculation, or whether attenuated microbes were injected

into sensitive animals, the greater the degree of refractoriness shown by the animal, the more rapidly the microbes were consumed by the leucocytes. In a non-resistant animal the microbes remained free; no such phenomenon as phagocytosis could be observed. It seemed, therefore, that the phagocytes were charged with the defence of the human organism, and entered into conflict with the parasites which infected the human frame. It might be said that there were diseases in which the microbes were to be met with in the cells specially, and that these microbes nevertheless proved fatal to the animal. In tuberculosis and in leprosy the bacilli were to be found in the cells, and the results were of the most serious kind, in spite of the intense phagocytosis induced by the microbes of these diseases. This fact proved that the phagocytes and all the other means of defence were, under certain conditions, and at certain times, powerless to effect any good results; they had done their best to take up the microbes, but these had adapted themselves to the interior of the cells, and had conquered. It was not sufficient that the microbes should be eaten up, it was essential that they should also be digested by the phagocytes. Even in those cases where the struggle was going against the human organism, these cells still were the aggressors. It had been frequently observed in tuberculosis and leprosy that the bacilli had been killed in the interior of certain of these cells. The theory asserted that a struggle occurred between the microbes and the cells, but it did not imply that the bacilli always won the day. Phagocytosis only occurred in immune animals; in animals susceptible to the disease it was either not to be observed, or it was incomplete.

He then proceeded to discuss the questions whether immunity was the consequence of this power of the cells to digest the virulent microbes. As had been said, the cells of a refractory animal took up the microbes, which, it would appear, under favourable circumstances remained inert in the interior of the cells.

Numerous facts had been alleged to show that the microbes at the time they were taken up by the phagocytes were not degenerated, but were, on the contrary, in a condition of full activity. Thus, to take only one example, it had been found that in frogs the bacilli which had been taken up by the lecocytes remained alive within the protoplasm of the cell; this was apparent from their movements. In lymph taken from the body of a pigeon, numerous bacilli were to be seen imprisoned in the leucocytes, and these bacilli could be watched growing, actually under the eye of the observer, within the interior of dead phagocytes; they could be seen to elongate, to push out the protoplasm, distort the form of the cell, and finally to make their escape. Another demonstration of the importance of the action of the phagocytes was afforded by the fact that even in immune animals the microbes were found to increase when kept out of the reach of the leucocytes; thus, if a rabbit were inoculated in the anterior chamber of the eye, where there were no cells, the bacteria grew freely, and their development was only checked when the leucocytes had after a time migrated in large numbers, and began to take the microbes into their interior. It thus appeared that phagocytosis was a very general phenomenon, and one which was very efficacious in checking the advance of the organisms; when it failed, the individual succumbed to the virulence of the bacteria. The question remained, What was the mysterious force which attracted the cells towards the microbes? Why were the leucocytes, which in immune animals destroyed the microbes, incapable of seizing upon them in non-immune animals?

In 1883, Metchnikoff propounded his theory of phagocytosis. This theory rested on two assumptions: first, that the cells were attracted to the microbes in virtue of a special sensibility manifested towards all foreign bodies introduced into the tissues; the second was that this power of seizing upon the virulent microbes in immune animals originated in a habit formed during the earlier struggle with the attenuated virus with which the animal had been previously inoculated. The behaviour of the leucocytes might be more readily explained by assuming that leucocytes had the property, analogous to that possessed by the zoosperms of the myxomycetes—namely, that of being attracted by certain bodies and repelled by others. MM. Massart and Bordet had proved that the products of the microbes exerted a very marked chemical action on the phagocytes. When a virus was introduced into the body, it proliferated, and secreted a substance which attracted the leucocytes; the more active the virus, the more energetic were the poisons elaborated by it, and the cells which penetrated to the point of inoculation were paralyzed in their action, and rendered incapable of taking up the microbes, which therefore proliferated without hindrance. Further, in certain diseases the virus produced a substance which was still more poisonous. In chicken cholera, for instance, the poison secreted by the microbes repelled the leucocytes from the point of inoculation; it thus came about that phagocytes were never found in this particular affection. This, however, was not the case with animals which had been rendered immune either by inoculation of the attenuated virus, or by the injection of a suitable dose of bacterial products. If the animal were given a strong virus, phagocytes were attracted to the point of inoculation, and these possessed the power of taking up the microbes before they had time to elaborate effective doses of their toxic material. It was, therefore, at the commencement of the disease that the critical struggle took place. If the leucocytes could not accomplish this at the beginning of the malady, their action at a later period would be useless, since the microbes would have produced enough poison to paralyze their activity. Every cause, therefore, that prevented the access of leucocytes to the point of inoculation facilitated infection. The theory of immunity propounded by M. Metchnikoff did not exclude the possibility of there being other means of protecting the organism, but it simply proved that phagocytosis had a wider sphere of action, and was more efficacious, than any other means of protecting the organism. It seemed to explain all the facts, and was, moreover, eminently suggestive. It was in this way that the knowledge of microbic poisons and chemical inoculation had thrown light on what would otherwise have been obscure. Far from being shaken by the theories which were opposed to it, this theory of Metchnikoff's had gained by the opposition which it has met, and that was a guarantee of its soundness.

Dr. Buchner, of Munich, after giving a general account of the various theories of immunity, criticized freely Metchnikoff's views. The main objections he brought forward were as follows:—

(1) Many observers failed to notice any destruction of bacilli by phagocytes, when naturally immune animals, such as white rats or pigeons, were inoculated with anthrax.

(2) In diseases ending fatally, such as tuberculosis, mice-septicæmia, &c., the micro-organisms were frequently found in the interior of phagocytes.

(3) The experiments of Petruchky, Baumgarten, Pekelharing, and others seemed to show that the bacilli of anthrax perished in the living fluids of immune animals even when the bacilli were protected against the attacks of white corpuscles.

Metchnikoff, however, denied this, and proved that the living fluids of immune white rats form a most excellent cultivating medium for the bacilli of anthrax. These observations of Metchnikoff, according to Buchner, might be explained by the fact that Metchnikoff in his experiments introduced more bacilli than could be destroyed by the living fluids of white rats, as a certain quantity of serum was able to destroy only a very small quantity of micro-organisms. Speaking of the experiments made by his pupils Ibener and Roeder, he stated that, when a certain kind of micro-organisms were placed into a given quantity of serum, the micro-organisms might either be destroyed *in toto*, or reproduce themselves in large numbers according to the number of micro-organisms introduced in the first place into the serum. When, instead of placing the micro-organisms directly in contact with the serum, the micro-organisms were wrapped up in sterilised cotton-wool, it was found that the bacilli, so protected against the temporary harmful influence of serum, began to grow luxuriantly at the end of twenty-four hours. The bactericidal power of serum disappeared, therefore, shortly after death.

Massart, Bordet, and Gabritchewsky had previously proved that the emigration of leucocytes to the spot where the virus was introduced was due to the attracting influence (positive chemotaxis) of the chemical poisons secreted by micro-organisms, but he (Buchner) was of opinion that the substances dissolved in the cultures have hardly any action on leucocytes, but that this attracting influence on leucocytes was due to the protein present in bacterial cells themselves. Whereas the products of the metabolism of micro-organisms had little or no attracting influence on the leucocytes, the proteins themselves attracted the cells most powerfully.

As long as the bacterial cells were active and capable of reproducing themselves actively, the proteins were contained in the cells, and these poisons only left the cells when the latter

Digitized by Google

organism. This criticism also applied to M. Buchner's experiments, which he had communicated to this meeting; he insisted on the fact that, in order to assure one's self thoroughly of the bactericidal property of the serum, it was necessary to take a small quantity of the culture, and spread it in a tube filled with serum. If, according to Dr. Buchner, one introduced a little of the culture wrapped in cotton-wool, the serum could no longer exercise its bactericidal power, and the microbe developed freely. Now, when one inoculated the bacillus under the skin of an animal, one introduced at the same time a small mass which did not spread freely in the blood or exudation, but remained localized at one spot. The experiments of Mr. Buchner, instead of furnishing an objection to the phagocyte theory, rather supported it.

Referring to the curative properties of the serum of white rats against anthrax, he had come to the conclusion that, whereas the living serum of white rats had no bactericidal action on anthrax, the dead serum of the same animals had marked bactericidal powers on the same micro-organism. When a mouse was inoculated with a mixture of the dead serum of a rat and anthrax bacilli, it nearly always died, although the disease lasted somewhat longer than usual. On examination of the point of inoculation it was found that the bacilli of anthrax did not grow quite so readily, and that an enormous number of leucocytes emigrated to the point of inoculation and took the bacilli into their interior and digested them. In tetanus, again, the leucocytes ate up considerable quantities of tetanus-spores and bacilli. Summing up his researches, he stated that whenever an animal recovered from an infectious disease this recovery was accompanied by a process of phagocytosis; whenever an animal died of an infectious disease the process of phagocytosis was absent or insufficient. The theory of phagocytes was strictly based on the principles of evolution as laid down by Darwin and Wallace.

After some remarks by Dr. Fodor, Dr. Cartwright Wood, Prof. Babes, Dr. Wright, and Dr. Arloing,

Dr. Roux, answering some remarks made by Prof. Emmerich, stated that, far from the preventive inoculations against anthrax and swine fever having been proved to be unsuccessful, agriculturists in France and other countries were making use of them daily, and the use of the various vaccins manufactured at the Institut Pasteur was increasing day by day.

Dr. Buchner congratulated Dr. Metchnikoff on his most important paper. He was of opinion, however, that the time for framing a complete theory of immunity had not come yet.

Sir Joseph Lister then stated that if anything were required to justify the existence of this Congress it would have been their sitting that day. The immense amount of valuable material which they had had on this most important subject had been such as to make all the members exceedingly grateful to those who had brought these matters before them.

THE BRITISH ASSOCIATION.

THE following is a list of the grants of money appropriated to scientific purposes by the General Committee at the Cardiff meeting, August 1891. The names of the members entitled to call on the General Treasurer for the respective grants are prefixed:

	£	s.	d.
A.—*Mathematics and Physics.*			
*Foster, Prof. Carey—Electrical Standards (partly renewed)	27	4	6
*McLaren, Lord—Meteorological Observations on Ben Nevis	50	0	0
*Symons, Mr. G. J.—Photographs of Meteorological Phenomena	15	0	0
*Cayley, Prof.—Pellian Equation Tables (partly renewed)	15	0	0
*Rayleigh, Lord—Tables of Mathematical Functions	15	0	0
*Fitzgerald, Prof. G. F.—Electrolysis	5	0	0
*Lodge, Prof.—Discharge of Electricity from Points	50	0	0
*Thomson, Sir W.—Seismological Phenomena of Japan	10	0	0
B.—*Chemistry and Mineralogy.*

SECTION E.

GEOGRAPHY.

OPENING ADDRESS BY E. G. RAVENSTEIN, F.R.G.S., F.S.S., PRESIDENT OF THE SECTION.

The Field of Geography.[1]

IT behoves every man from time to time to survey the field of his labours, and to render an account unto himself of the work he has accomplished, and of the tasks which still await him, in order that he may perceive whether the means employed hitherto are commensurate with the magnitude of his undertaking, and likely to lead up to the desired results. Such a survey of the "Field of Geography" I propose to make the subject of my address to-day. . . .

Whatever changes may have taken place respecting the aims of the geographer, it is very generally acknowledged that the portraiture of the earth's surface in the shape of a map lies within his proper and immediate domain. And there can be no doubt that a map possesses unique facilities for recording the fundamental facts of geographical knowledge, and that with a

[1] Pressure on our space compels us to omit some parts of this address.

Digitized by Google

clearness and perspicuity not attainable by any other method. You will not, therefore, think it strange if I deal at considerable length with the development of cartography, more especially as my own labours have in a large measure been devoted to that department of geographical work. An inspection of the interesting collection of maps of all ages which I am able to place before you will serve to illustrate what I am about to say on this subject. . . .

Ptolemy, like all great reformers, stood upon the shoulders of the men who had preceded him, for before a map like his could be produced much preliminary work had been accomplished. Parmenides of Elea (460 B.C.) had demonstrated that our earth was a globe, and Eratosthenes (276-196 B.C.) had approximately determined its size. Hipparchus (190-120), the greatest astronomer of antiquity, the discoverer of the precession of the equinoxes, and the author of a catalogue of stars, had transferred to our earth the auxiliary lines drawn by him across the heavens. He had taught cartographers to lay down places according to their latitude and longitude, and how to project a sphere upon a plane. It is to him we are indebted for the stereographic and orthographic projections of the sphere. Ptolemy himself invented the tangential conical projection.

The gnomon or sun-dial, an instrument known to the Chinese 600 years before Christ, had long been used for the determination of latitudes, and the results were relatively correct, although uniformly subject to an error of 16 minutes, which was due to the observers taking the altitude of the upper limb of the sun, when measuring the shadow cast by their dial, instead of that of the sun's centre.

It was known, likewise, that differences of longitude could be determined by the simultaneous observation of eclipses of the sun or moon, or of occultations of stars, and Hipparchus actually calculated ephemerides for six years in advance to facilitate computations. Ptolemy himself suggested the use of lunar distances. But so imperfect were the astrolabes and other instruments used by the ancient astronomers, and especially their time-keepers, that precise results are quite out of the question.

Ptolemy, in fact, contented himself with accepting eight latitudes determined by actual observation, of which four were in Egypt, whilst of the three longitudes known to him he only utilized one in the construction of his map. Unfortunately, the one selected proved the least accurate, being erroneous to the extent of 32 per cent., whilst the error of the two which he rejected did not exceed 13 per cent.[1] This want of judgment—pardonable, no doubt, under the circumstances—vitiated Ptolemy's delineation of the Mediterranean to a most deplorable extent, far more so than did his assumption that a degree only measured five hundred stades, when in reality it measures six hundred. For whilst the breadth of his Mediterranean, being dependent upon the relatively correct latitudes of Alexandria, Rhodes, Rome, and Massilia, fairly approximates the truth, its length is exaggerated to the extent of nearly 50 per cent., measuring 62° instead of 41° 40′. This capital error of Ptolemy is due therefore to the unfortunate acceptance of an incorrect longitude, quite as much as to an exaggeration of itinerary distances. It is probable that Ptolemy would have presented us with a fairer likeness of our great inland sea had he rejected observed latitudes and longitudes altogether, and trusted exclusively to itineraries and to such bearings as the mariners of the period could have supplied him with.

No copy of Ptolemy's original set of maps has reached us, for the maps drawn by Agathodæmon in the fifth century are, under the most favourable circumstances, merely reductions of Ptolemy's originals, or they are compiled from Ptolemy's "Geography," which, apart from a few explanatory chapters, consists almost wholly of lists of places, with their latitudes and longitudes. I am almost inclined to adopt the latter view—firstly, because of the very crude delineation of Egypt, for which country an accurate cadastral survey was available; and secondly, on account of the cylindrical projection on which these maps are drawn, although from Ptolemy's own statements we are justified in believing that he made use of a conical projection in the construction of his maps.

[1] The three longitudes are the following:—

	Result of ancient observations.	Adopted by Ptolemy.	Actual difference of longitude.
Arbela ...	45° E. of Carthage ...	45 ...	34
Babylon ...	12 30 E. of Alexandria ...	18 30′ ...	14 18′
Rome ...	20 E. of Alexandria ...	23 50′ ...	17 24′

An examination of Ptolemy's maps shows very clearly that they were almost wholly compiled from itineraries, the greater number of which their author borrowed from his predecessor Marinus. It shows, too, that Ptolemy's critical acumen as a compiler cannot be rated very high, and that he failed to utilize much information of a geographical nature which was available in his day. His great merit consisted in having taught cartographers to construct their maps according to a scientific method. This lesson, however, they were slow to learn, and centuries elapsed before they once more advanced along the only correct path, which Ptolemy had been the first to tread.
